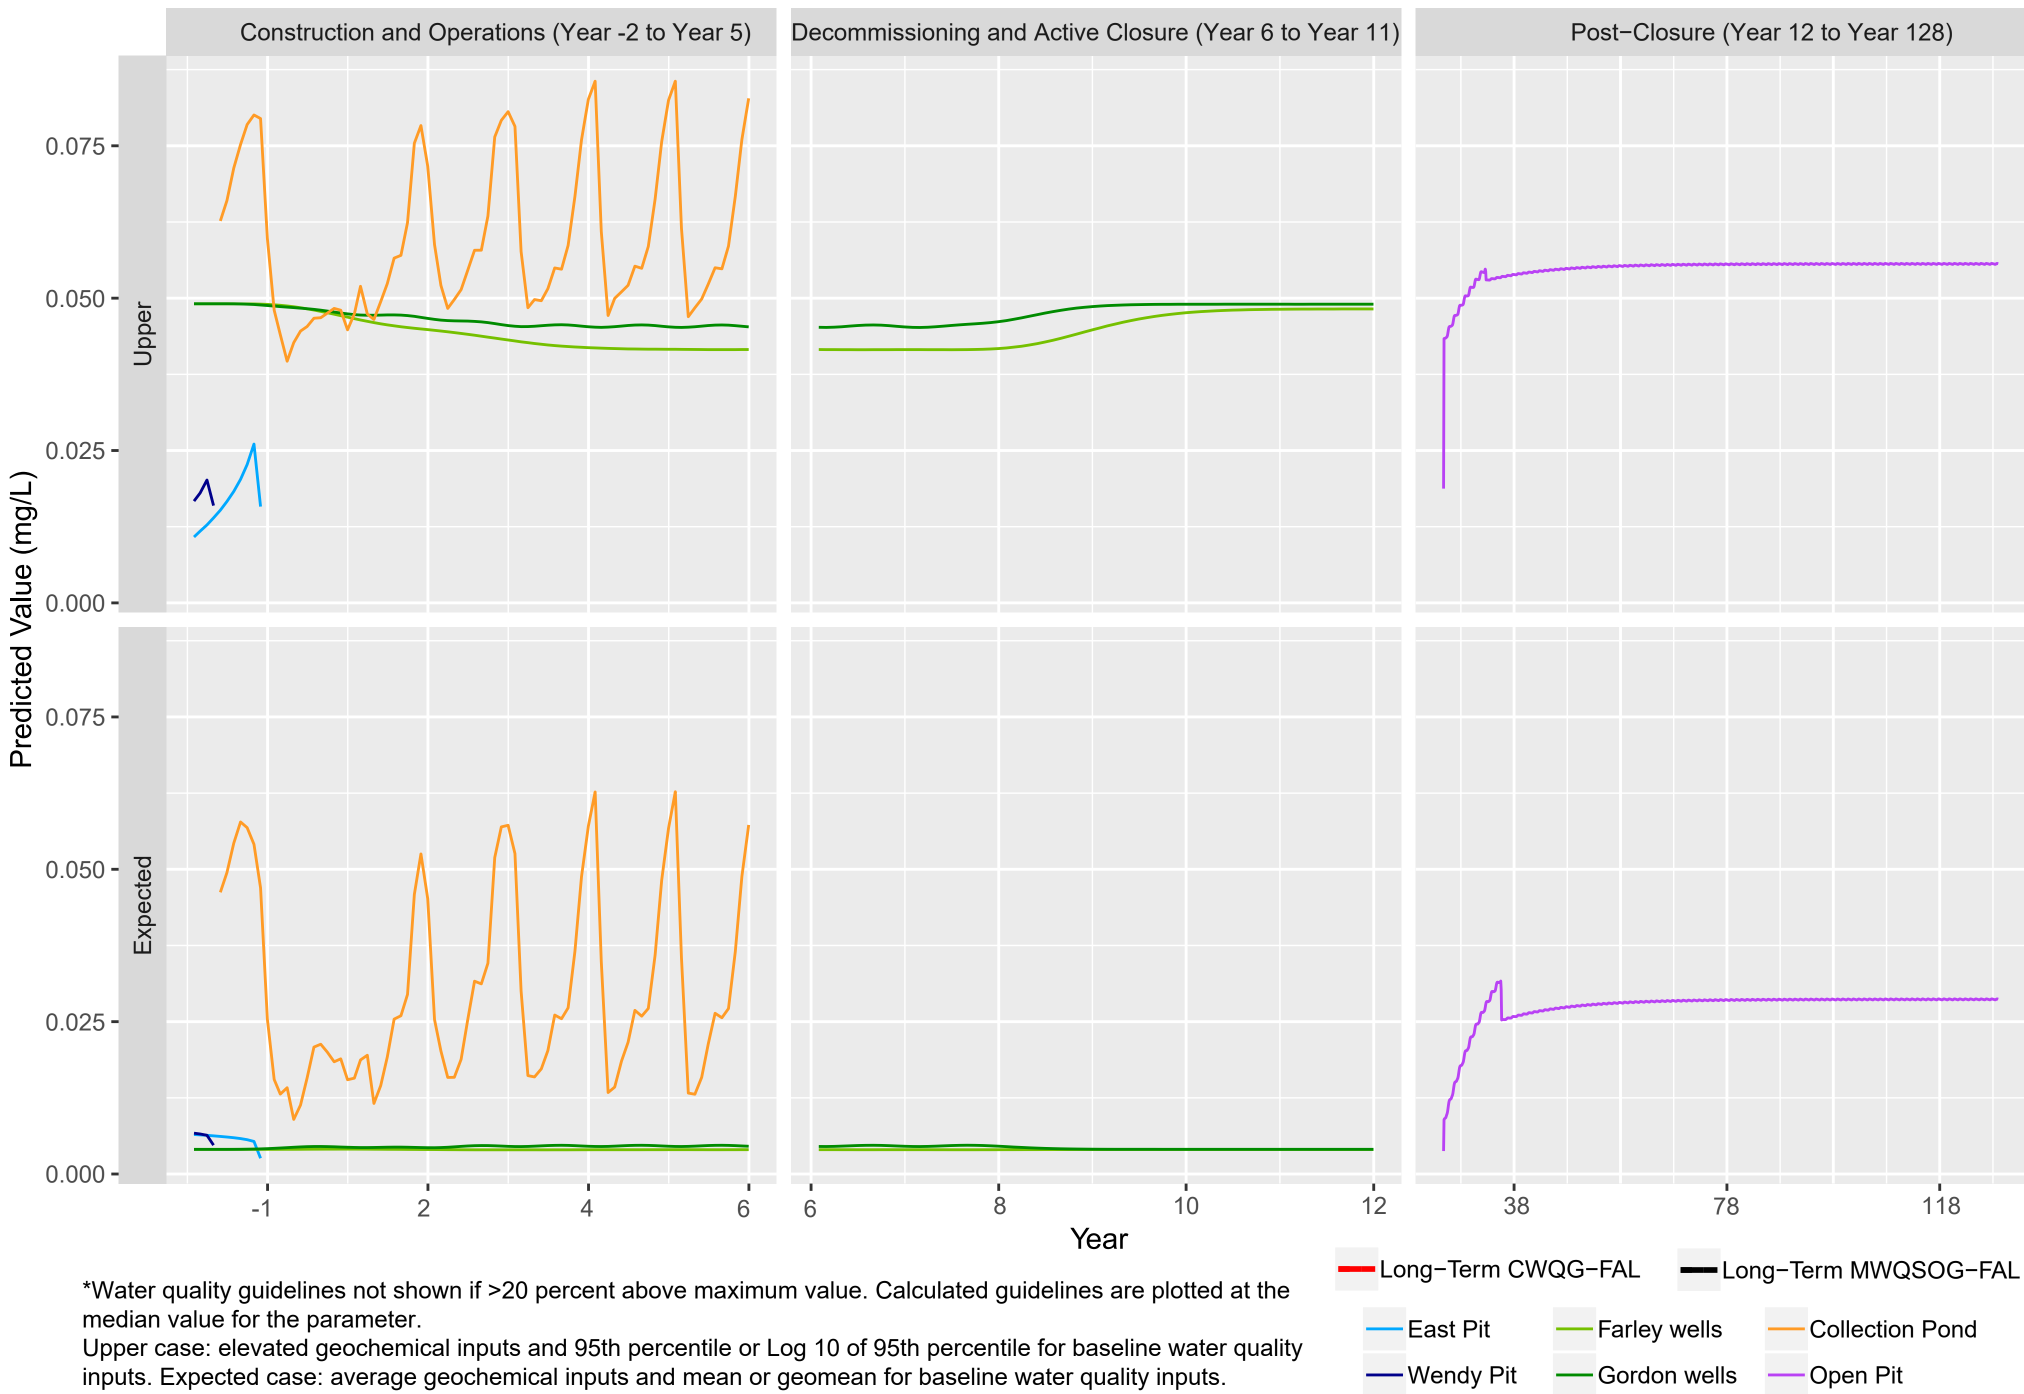
Appendix I TIME SERIES PLOTS

Appendix I-1: Gordon - Predicted Concentrations in Discharges

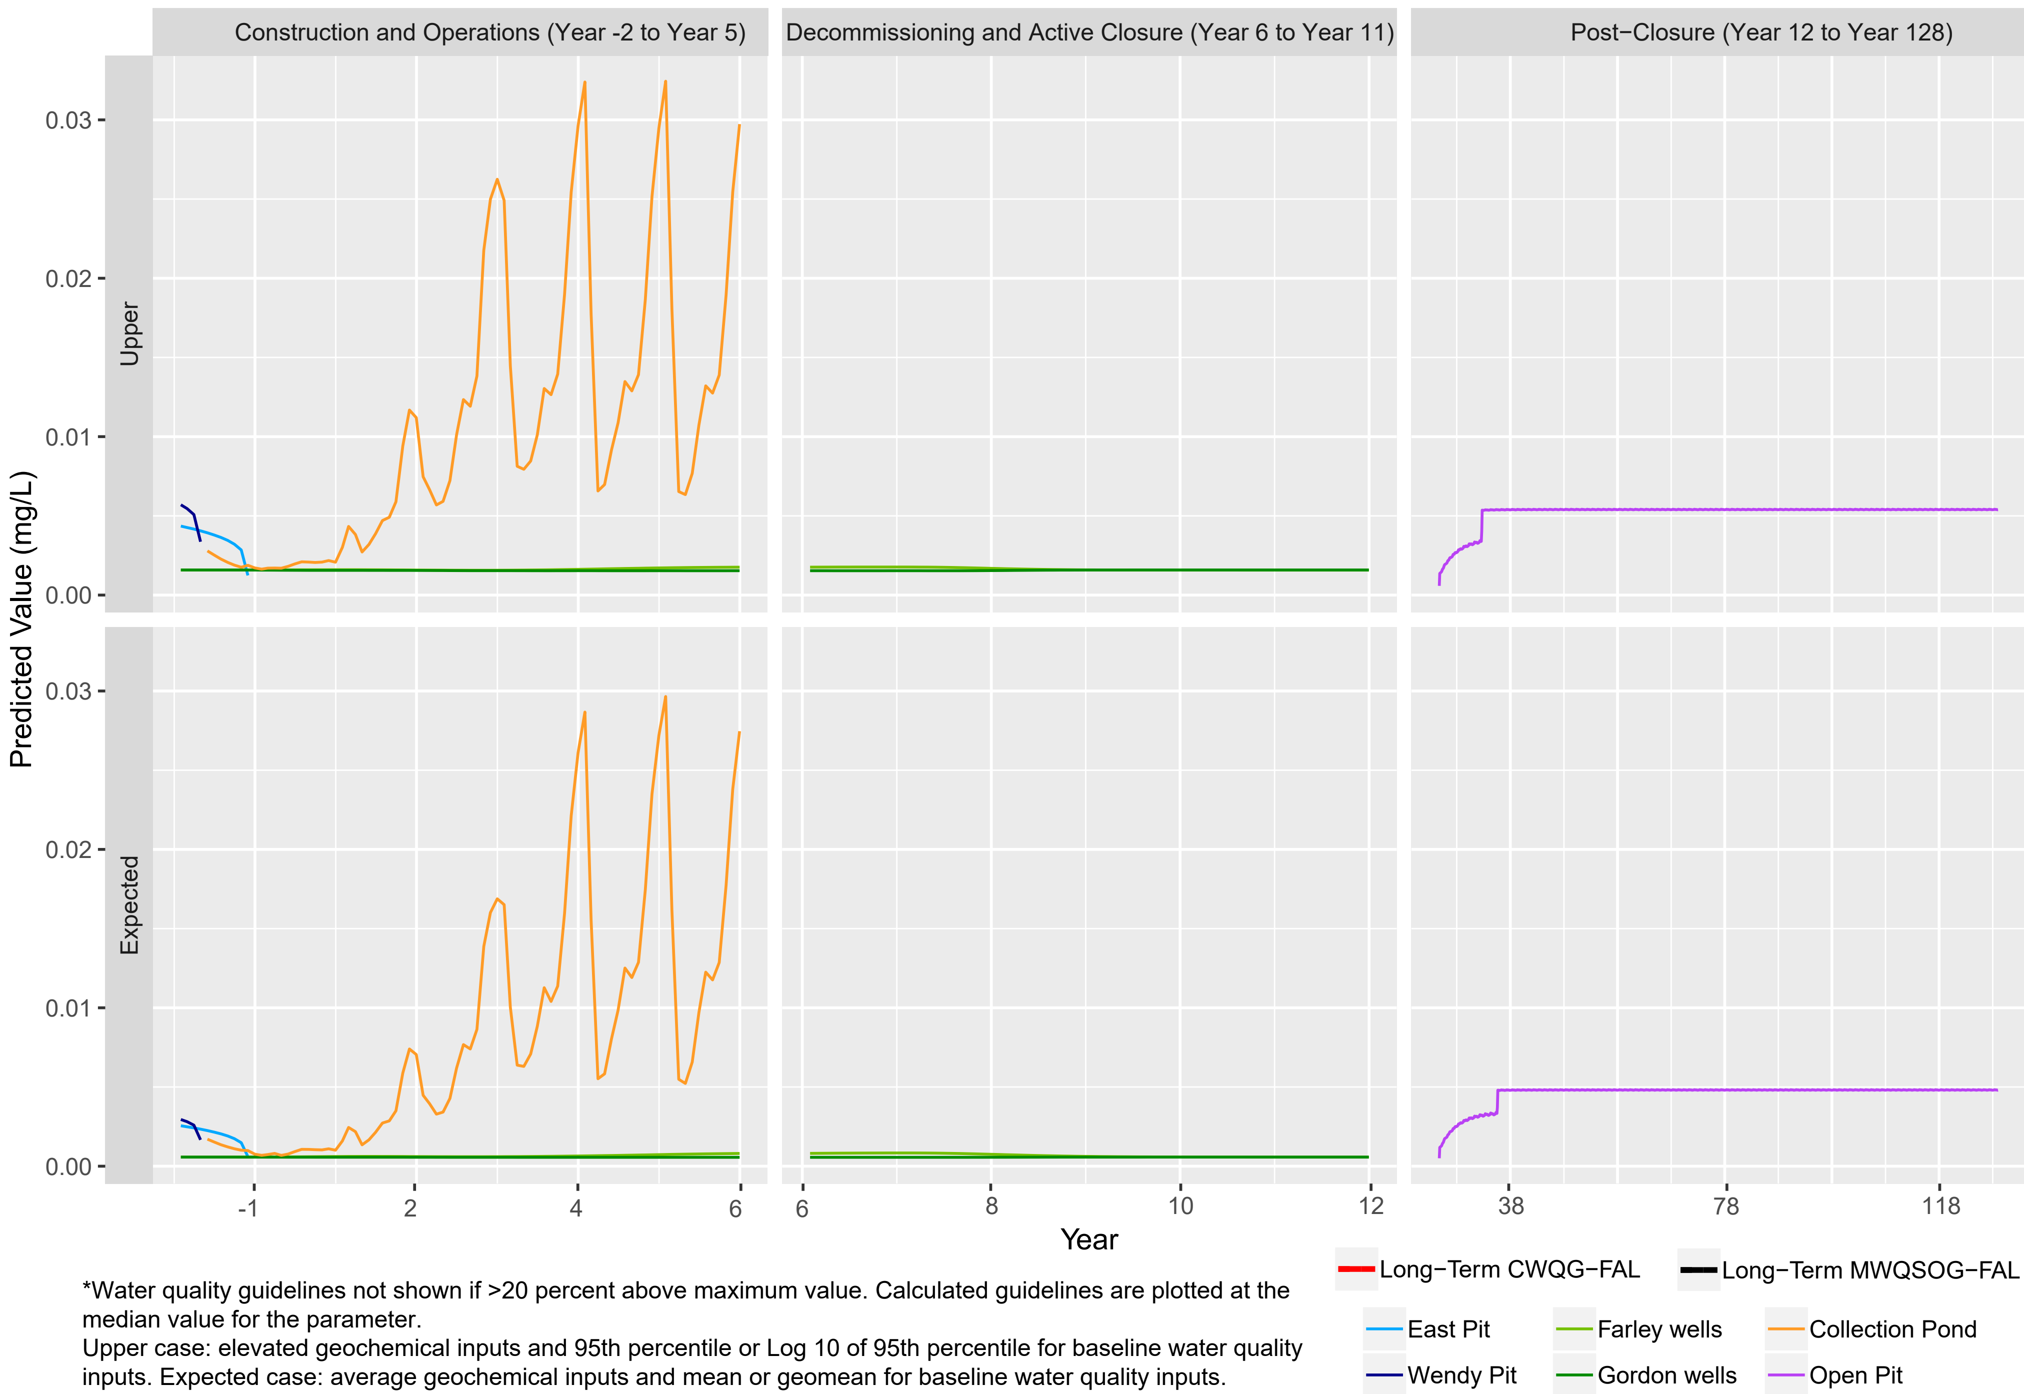
Aluminum, Total (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

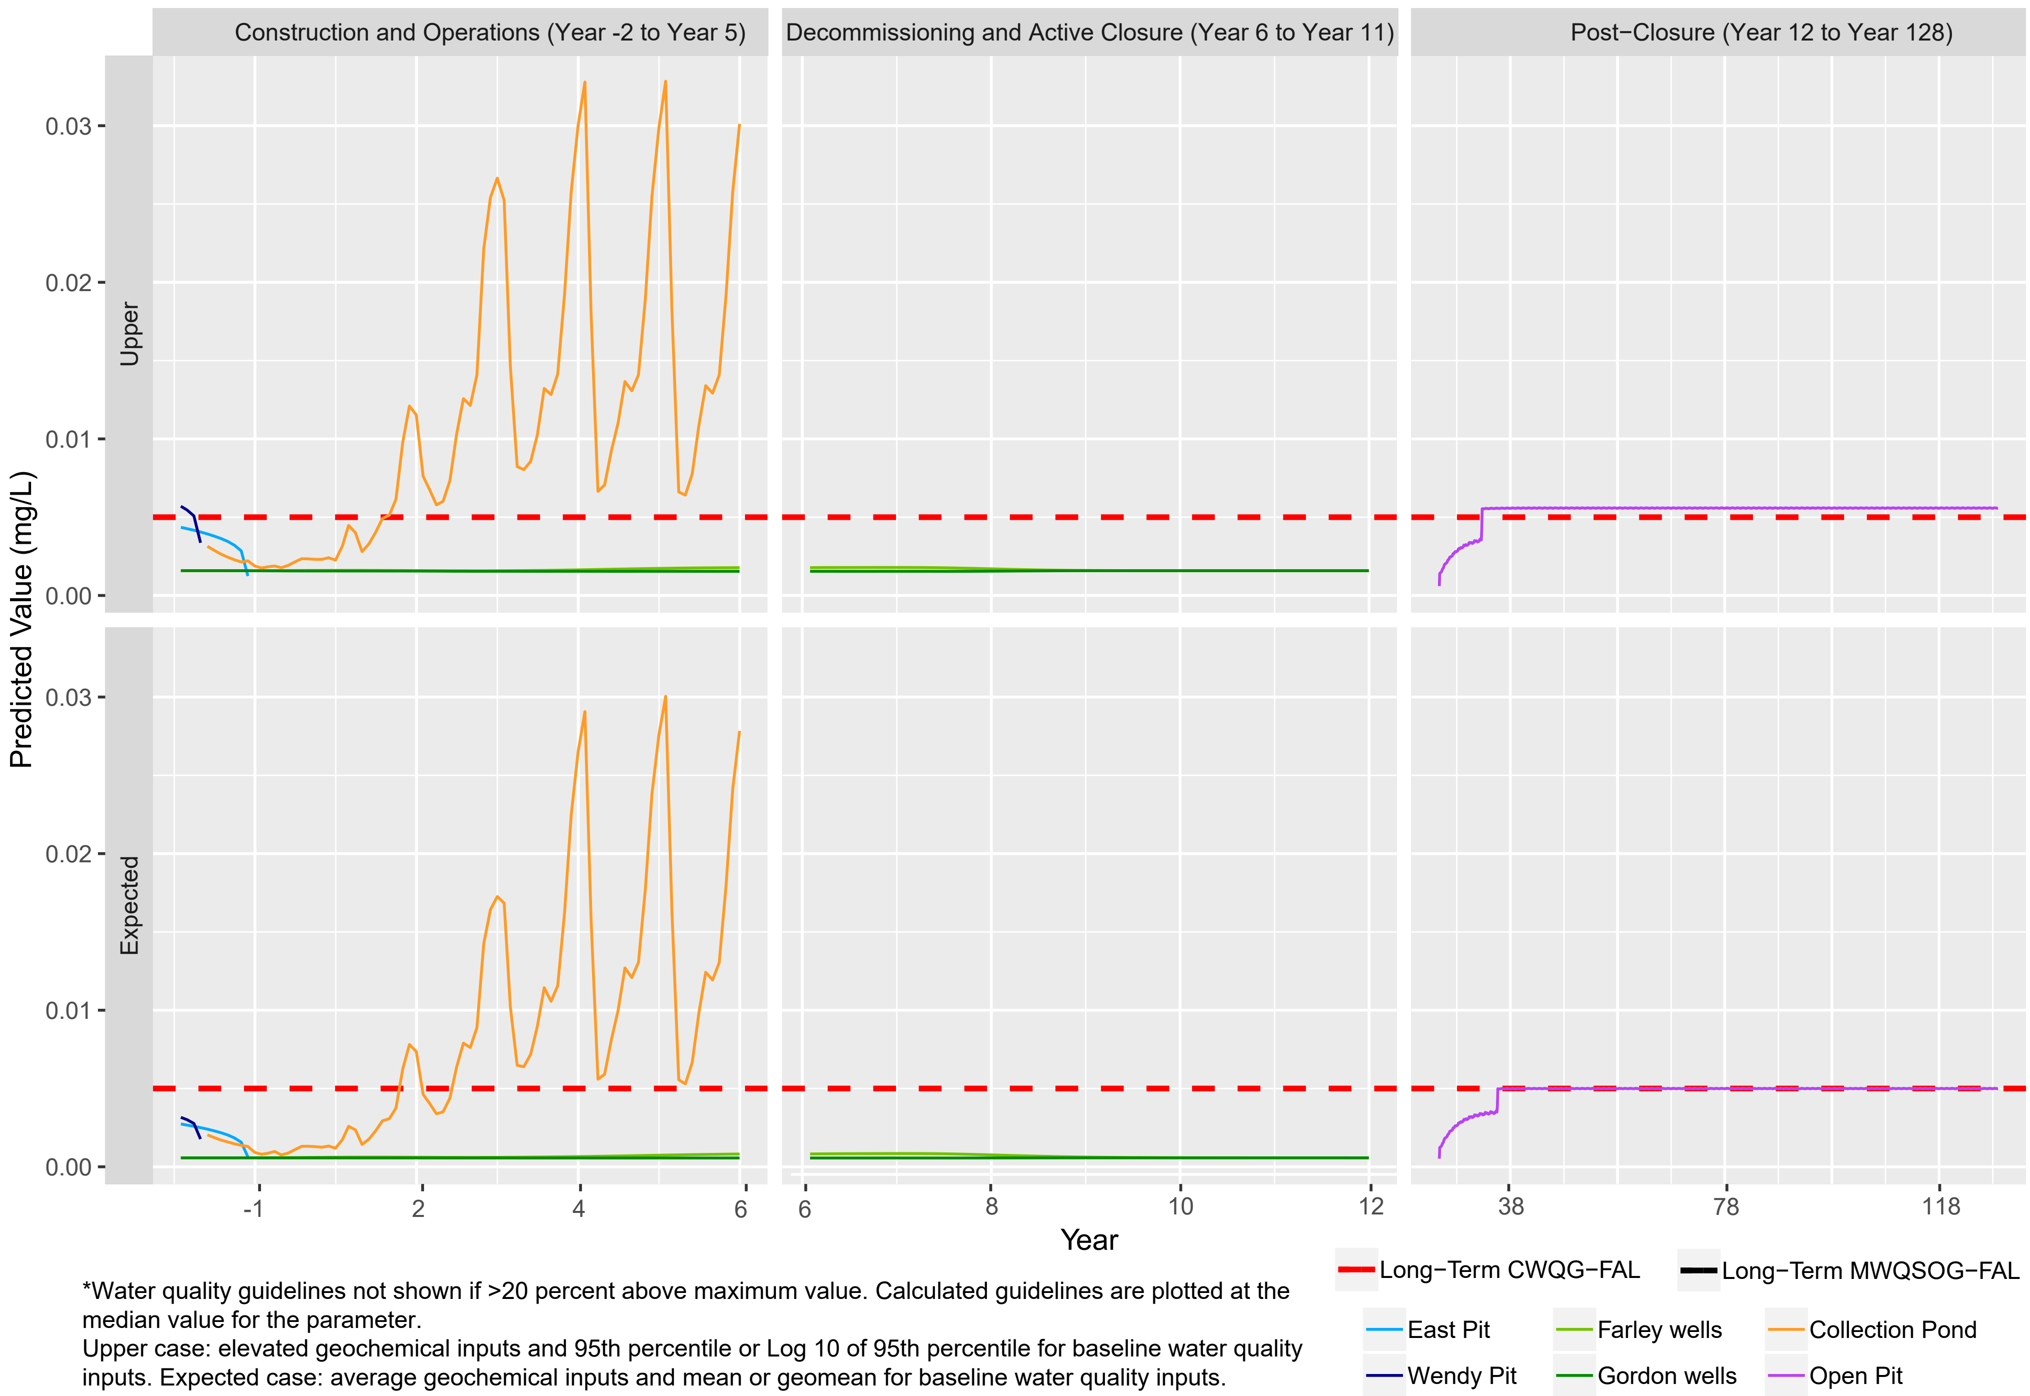
Arsenic, Dissolved (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

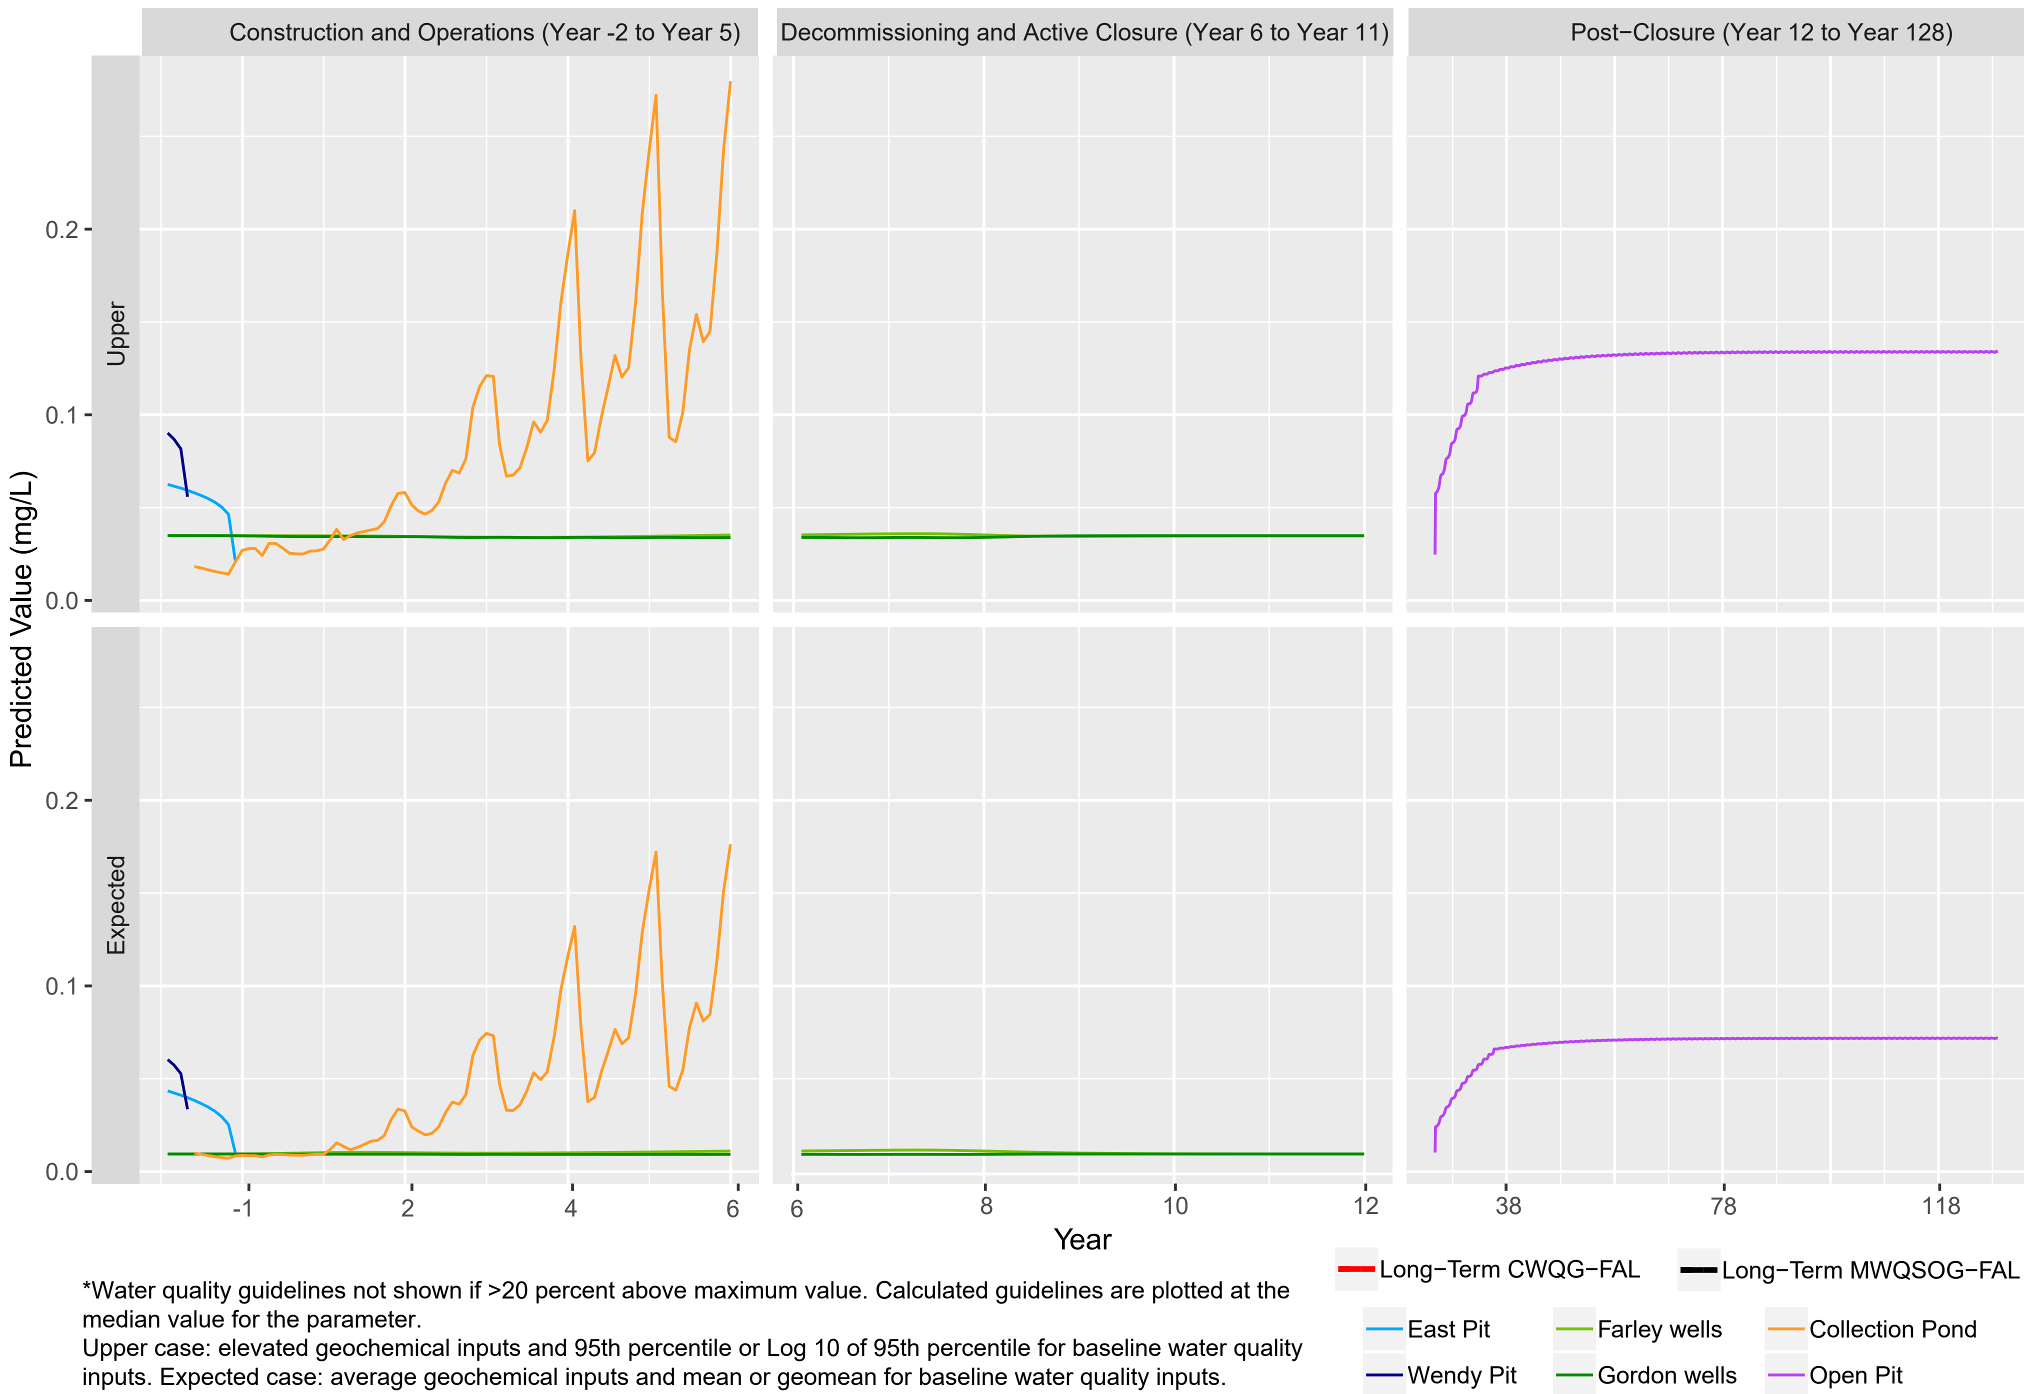
Arsenic, Total (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

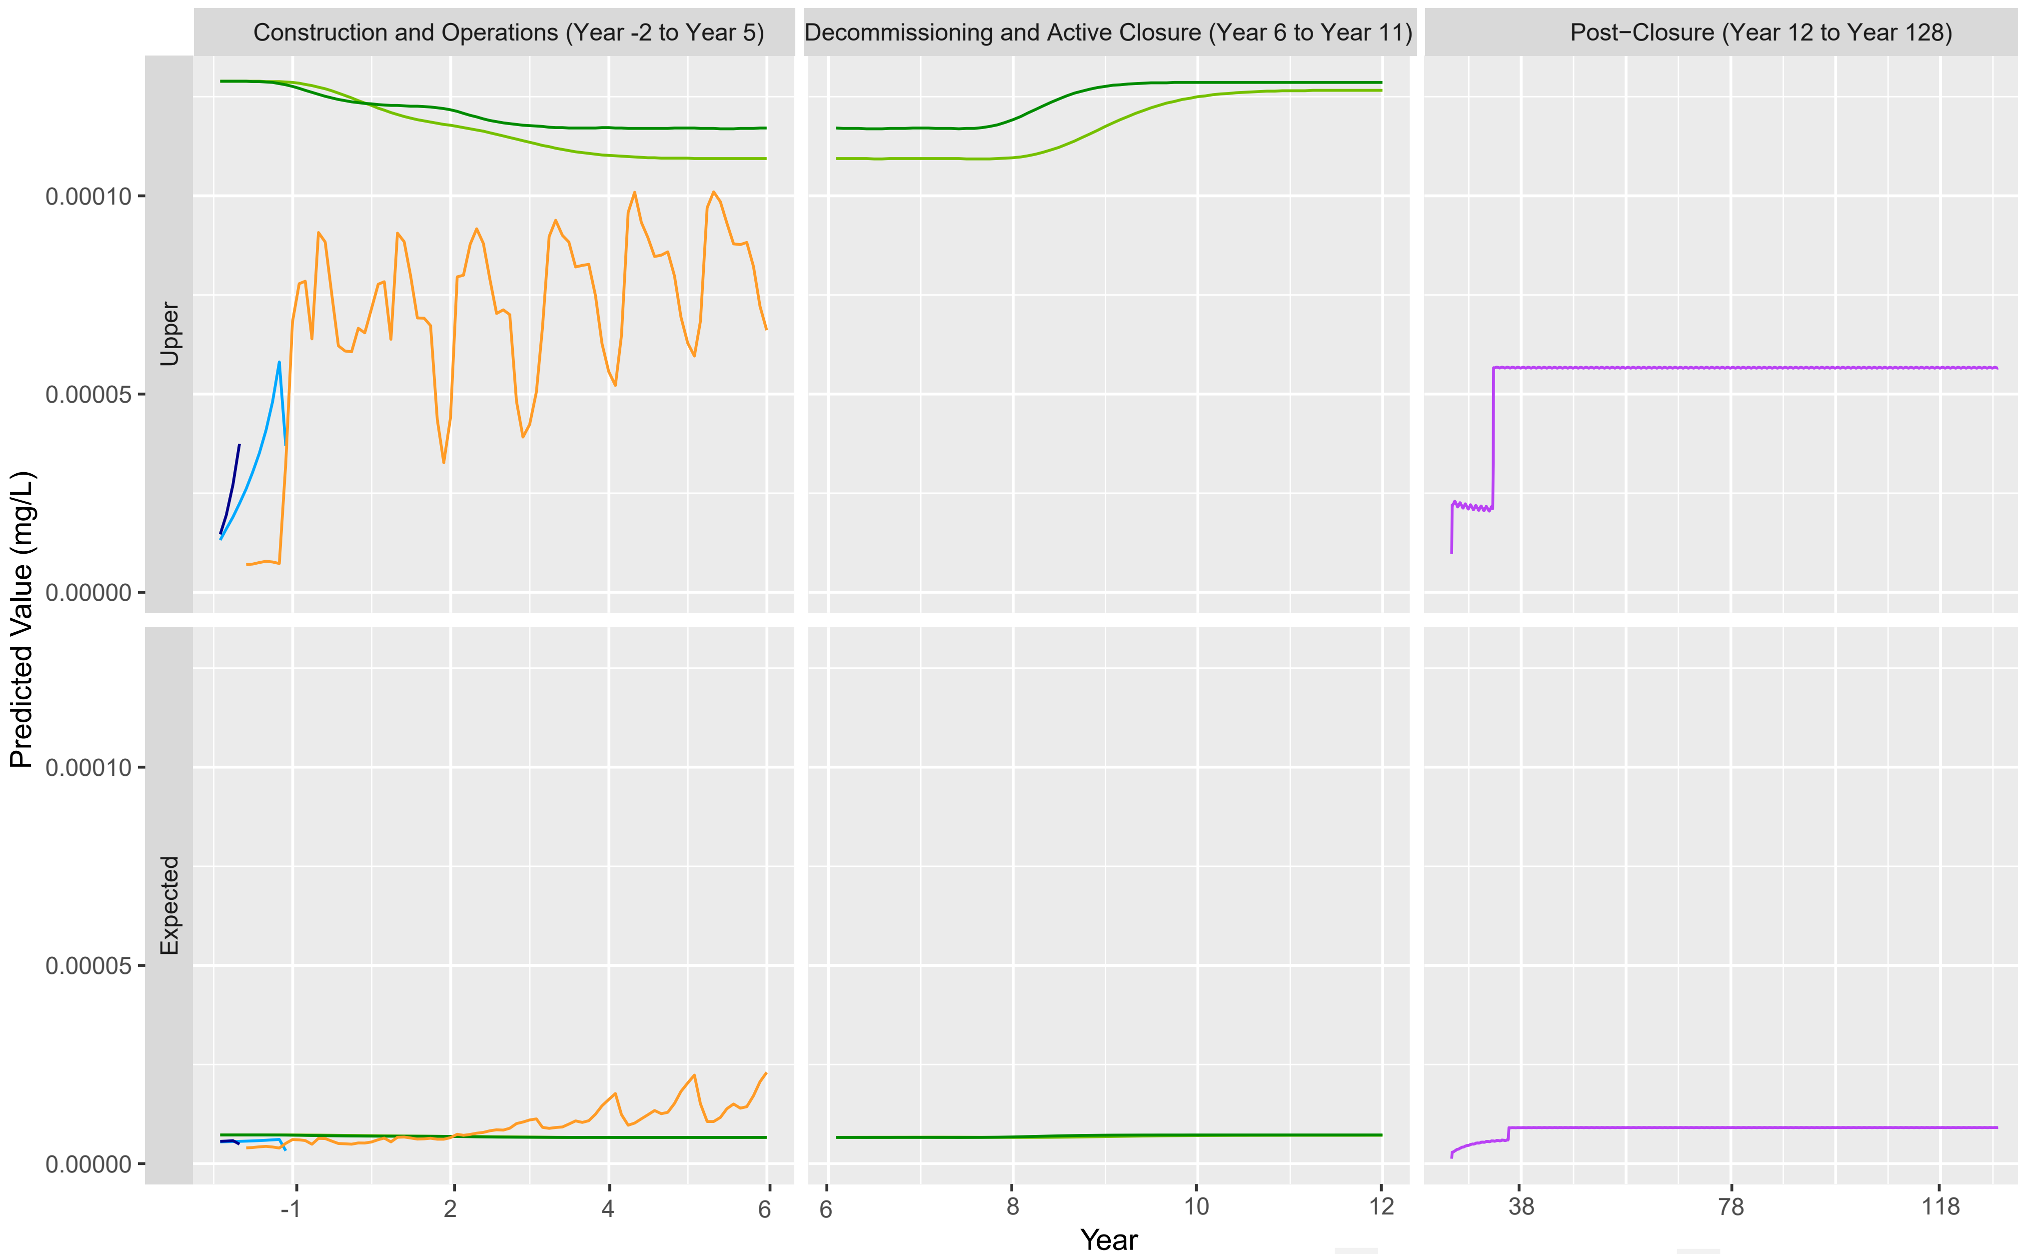
Boron, Total (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

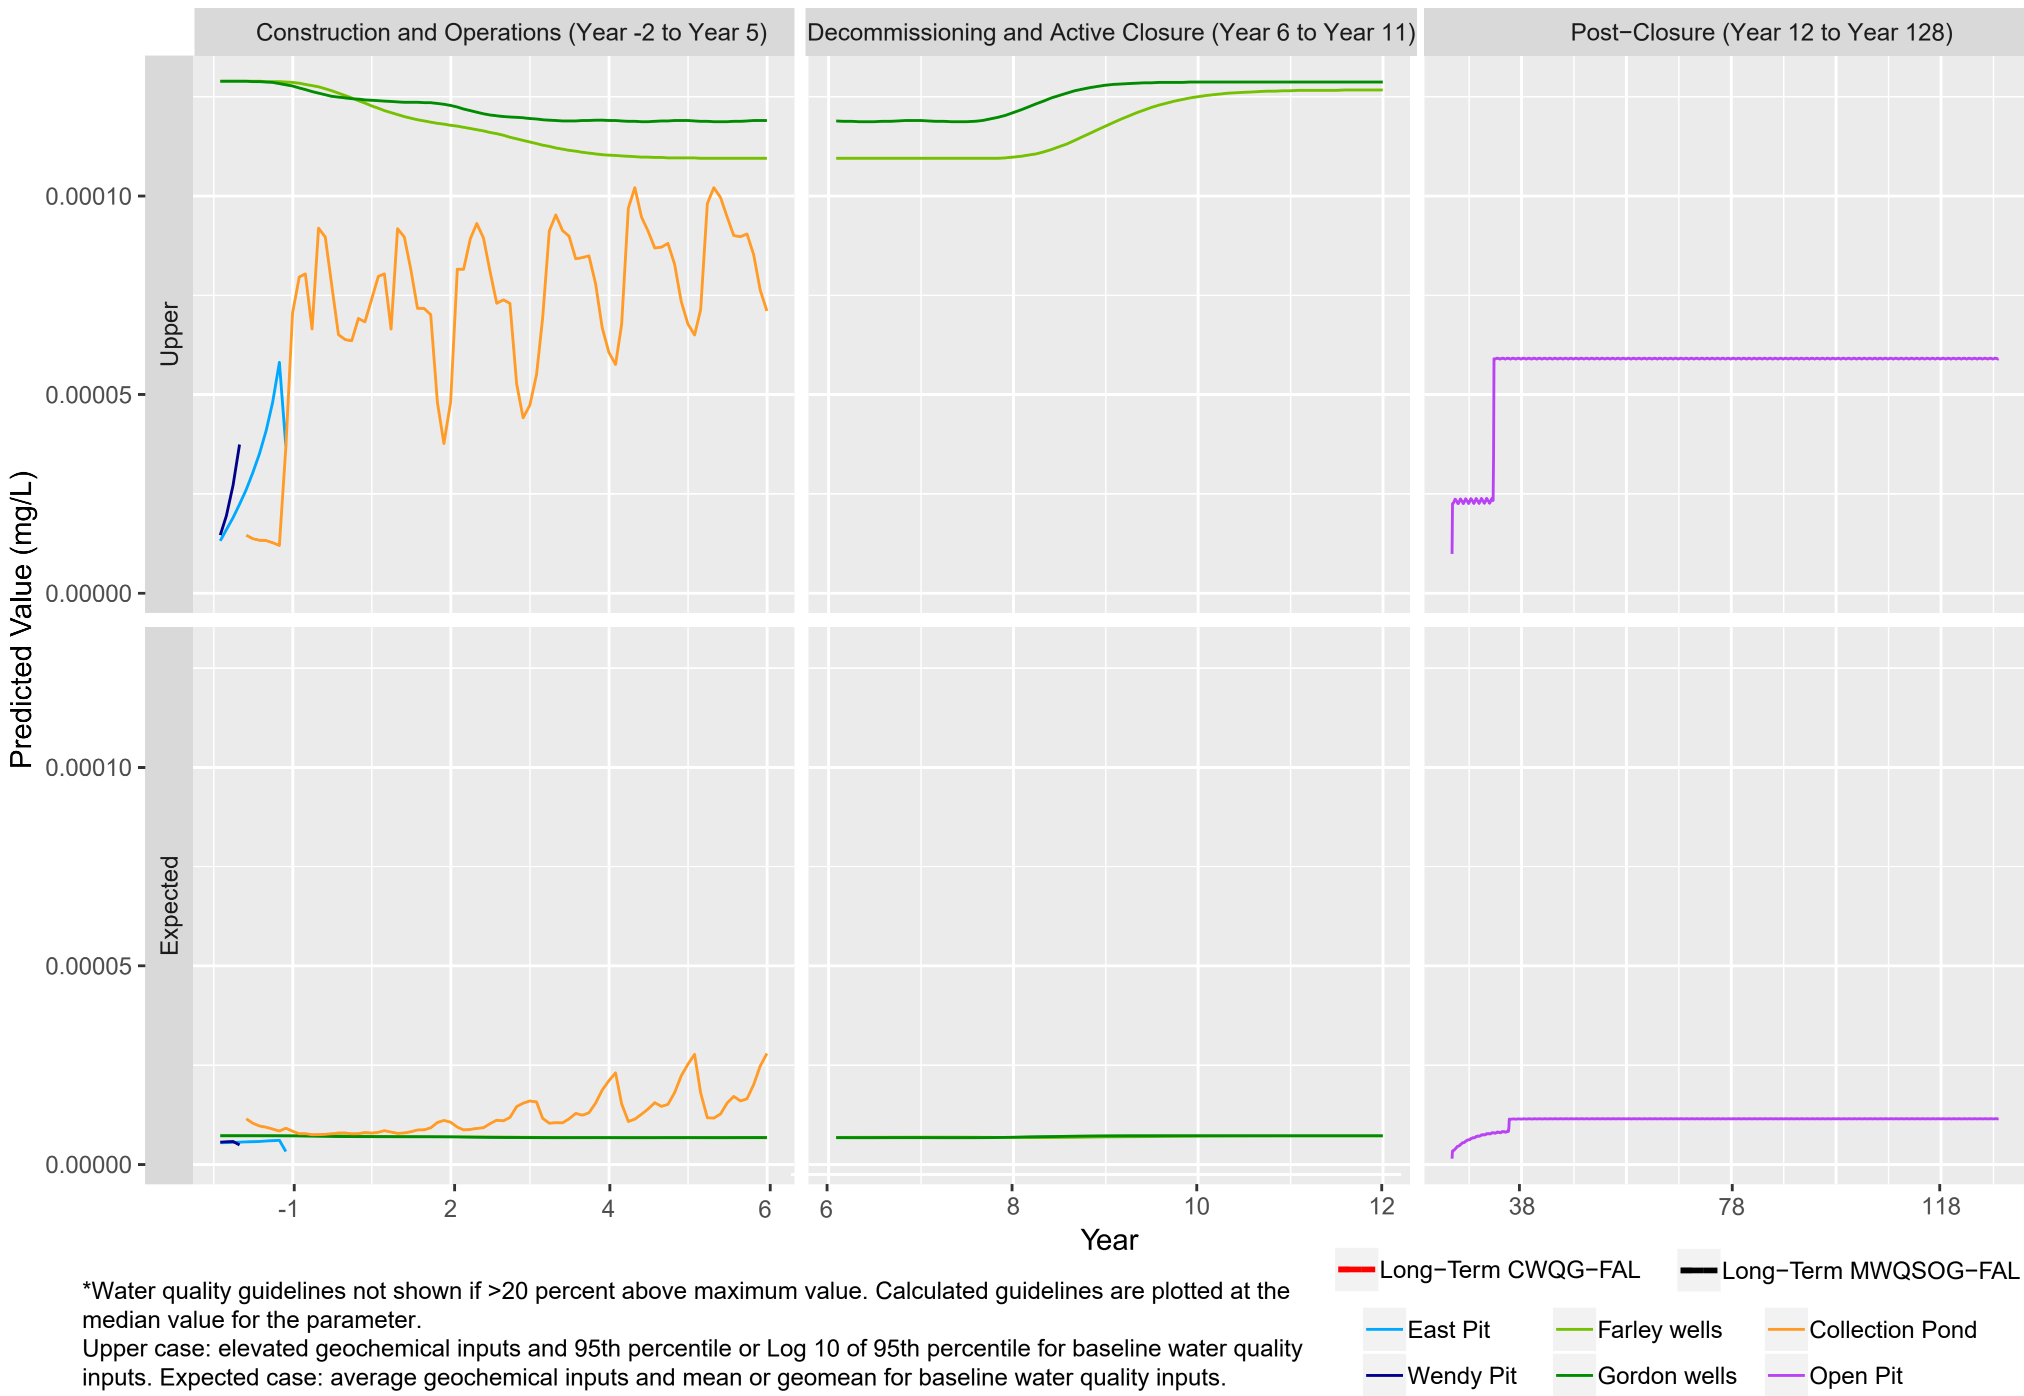
Cadmium, Dissolved (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

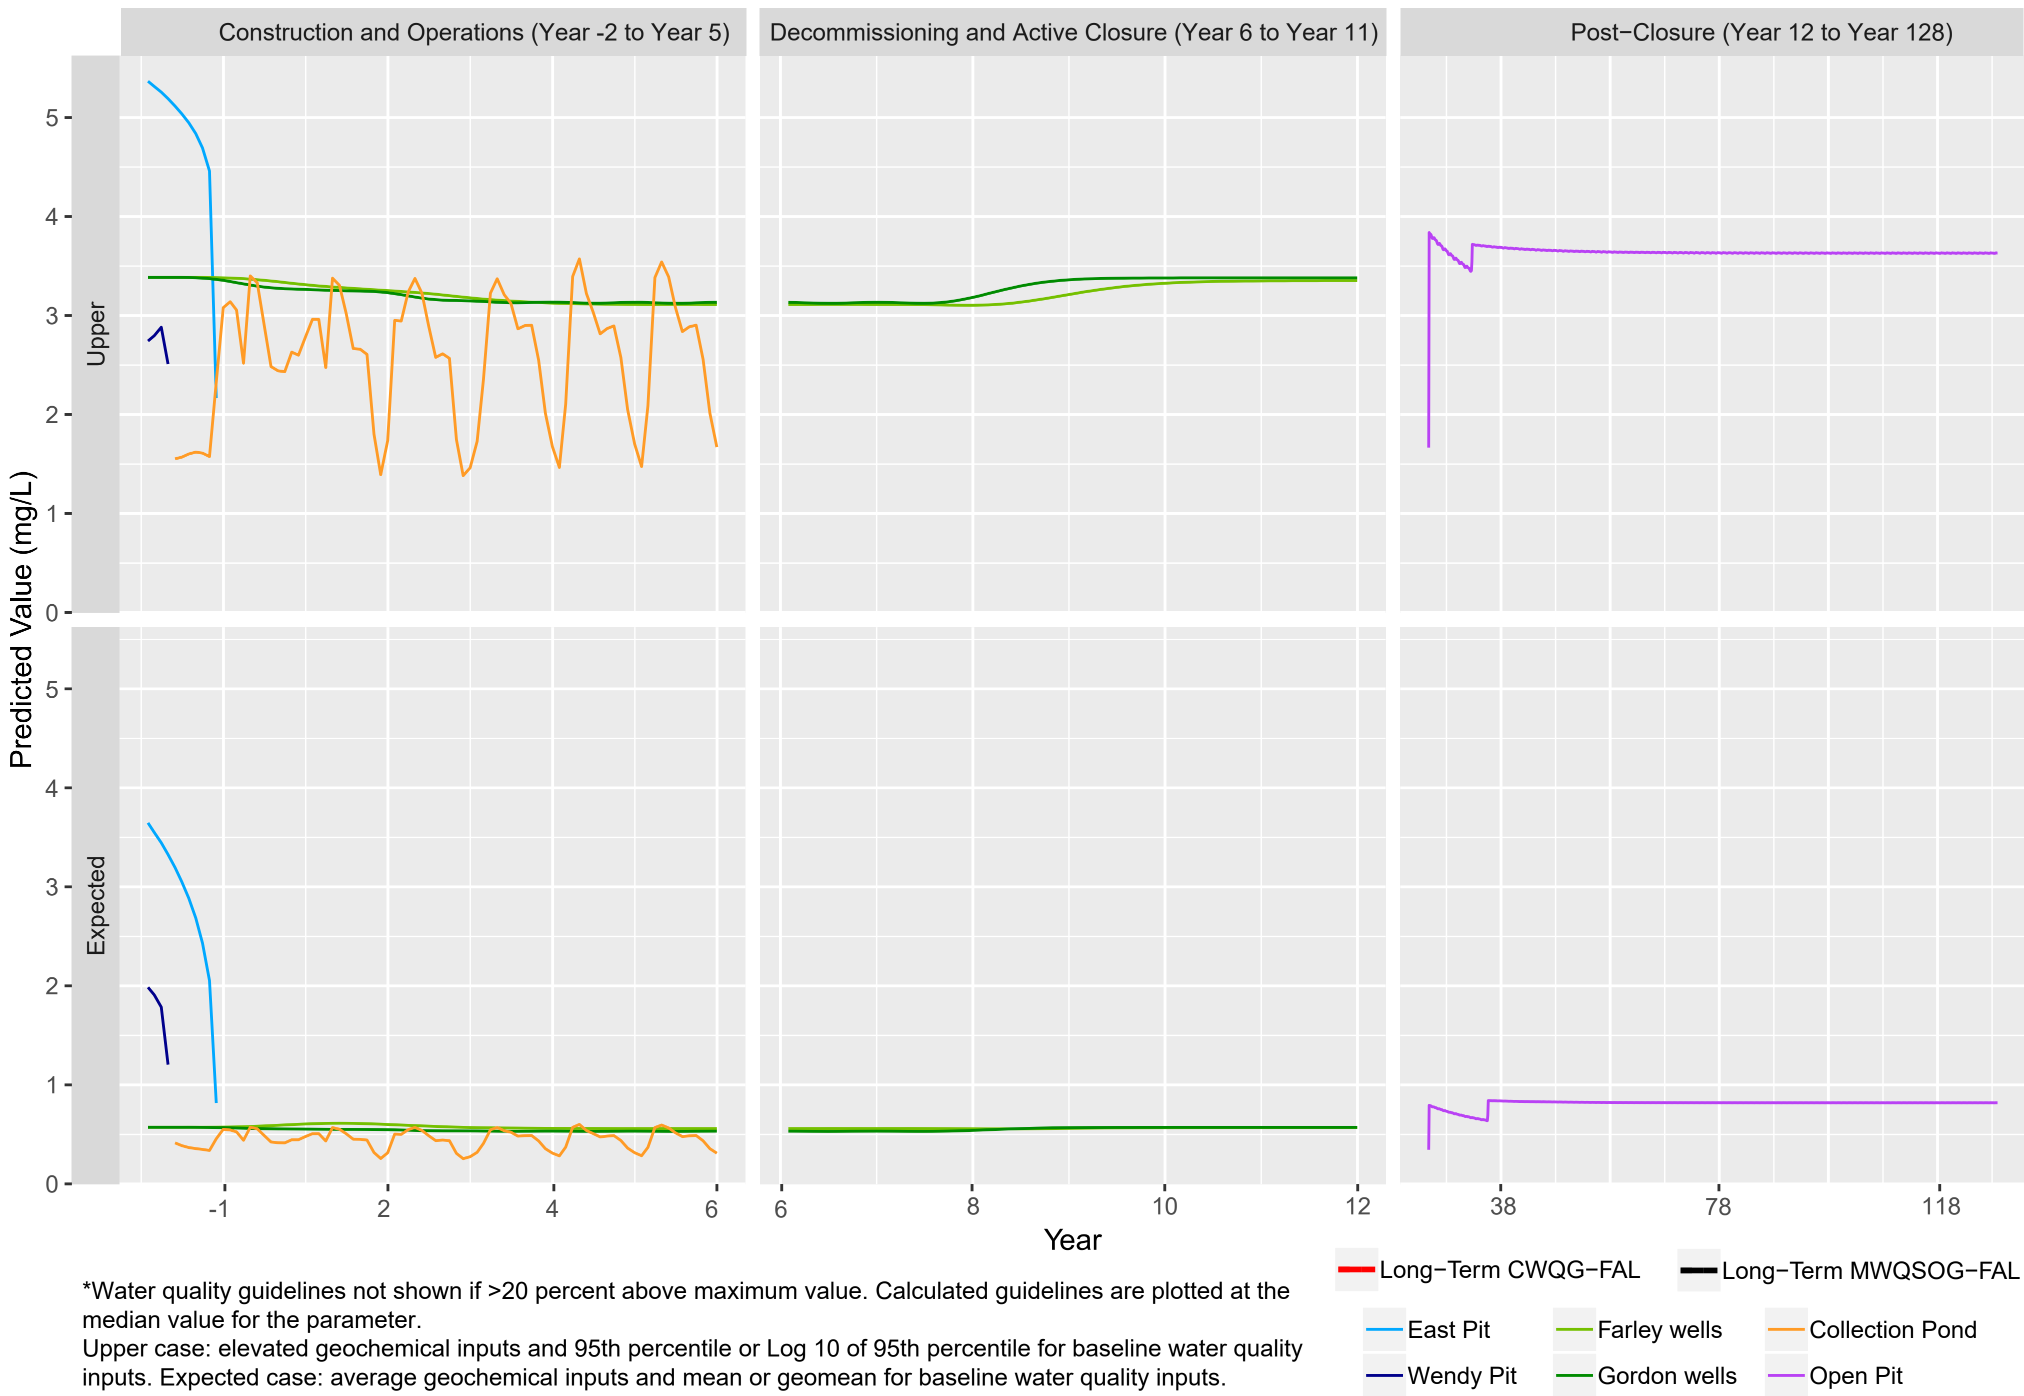
Cadmium, Total (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

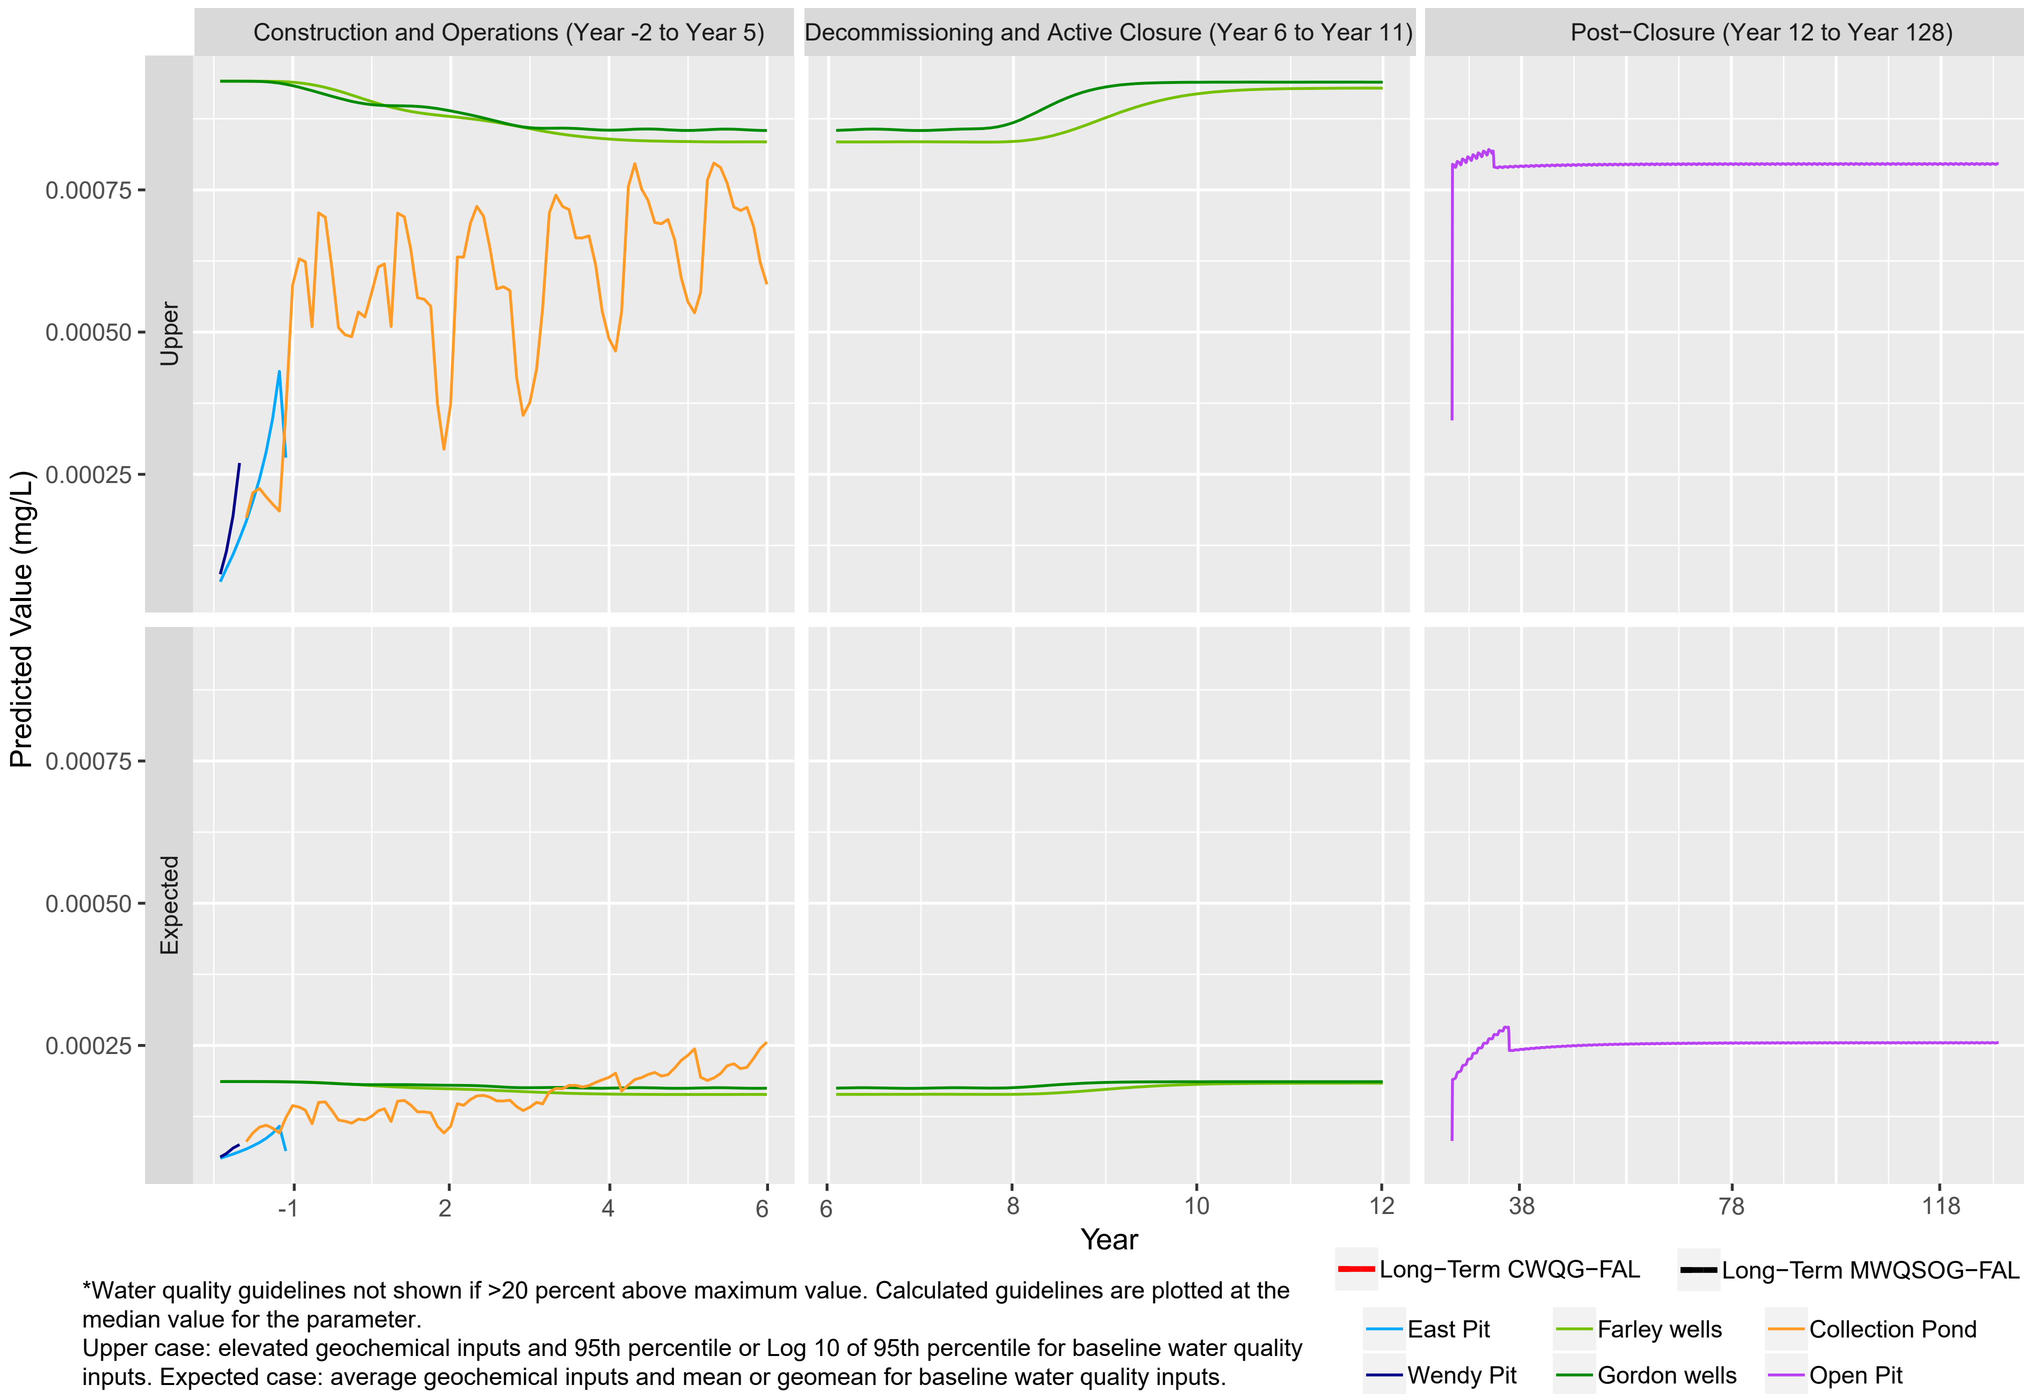
Chloride (Cl) (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

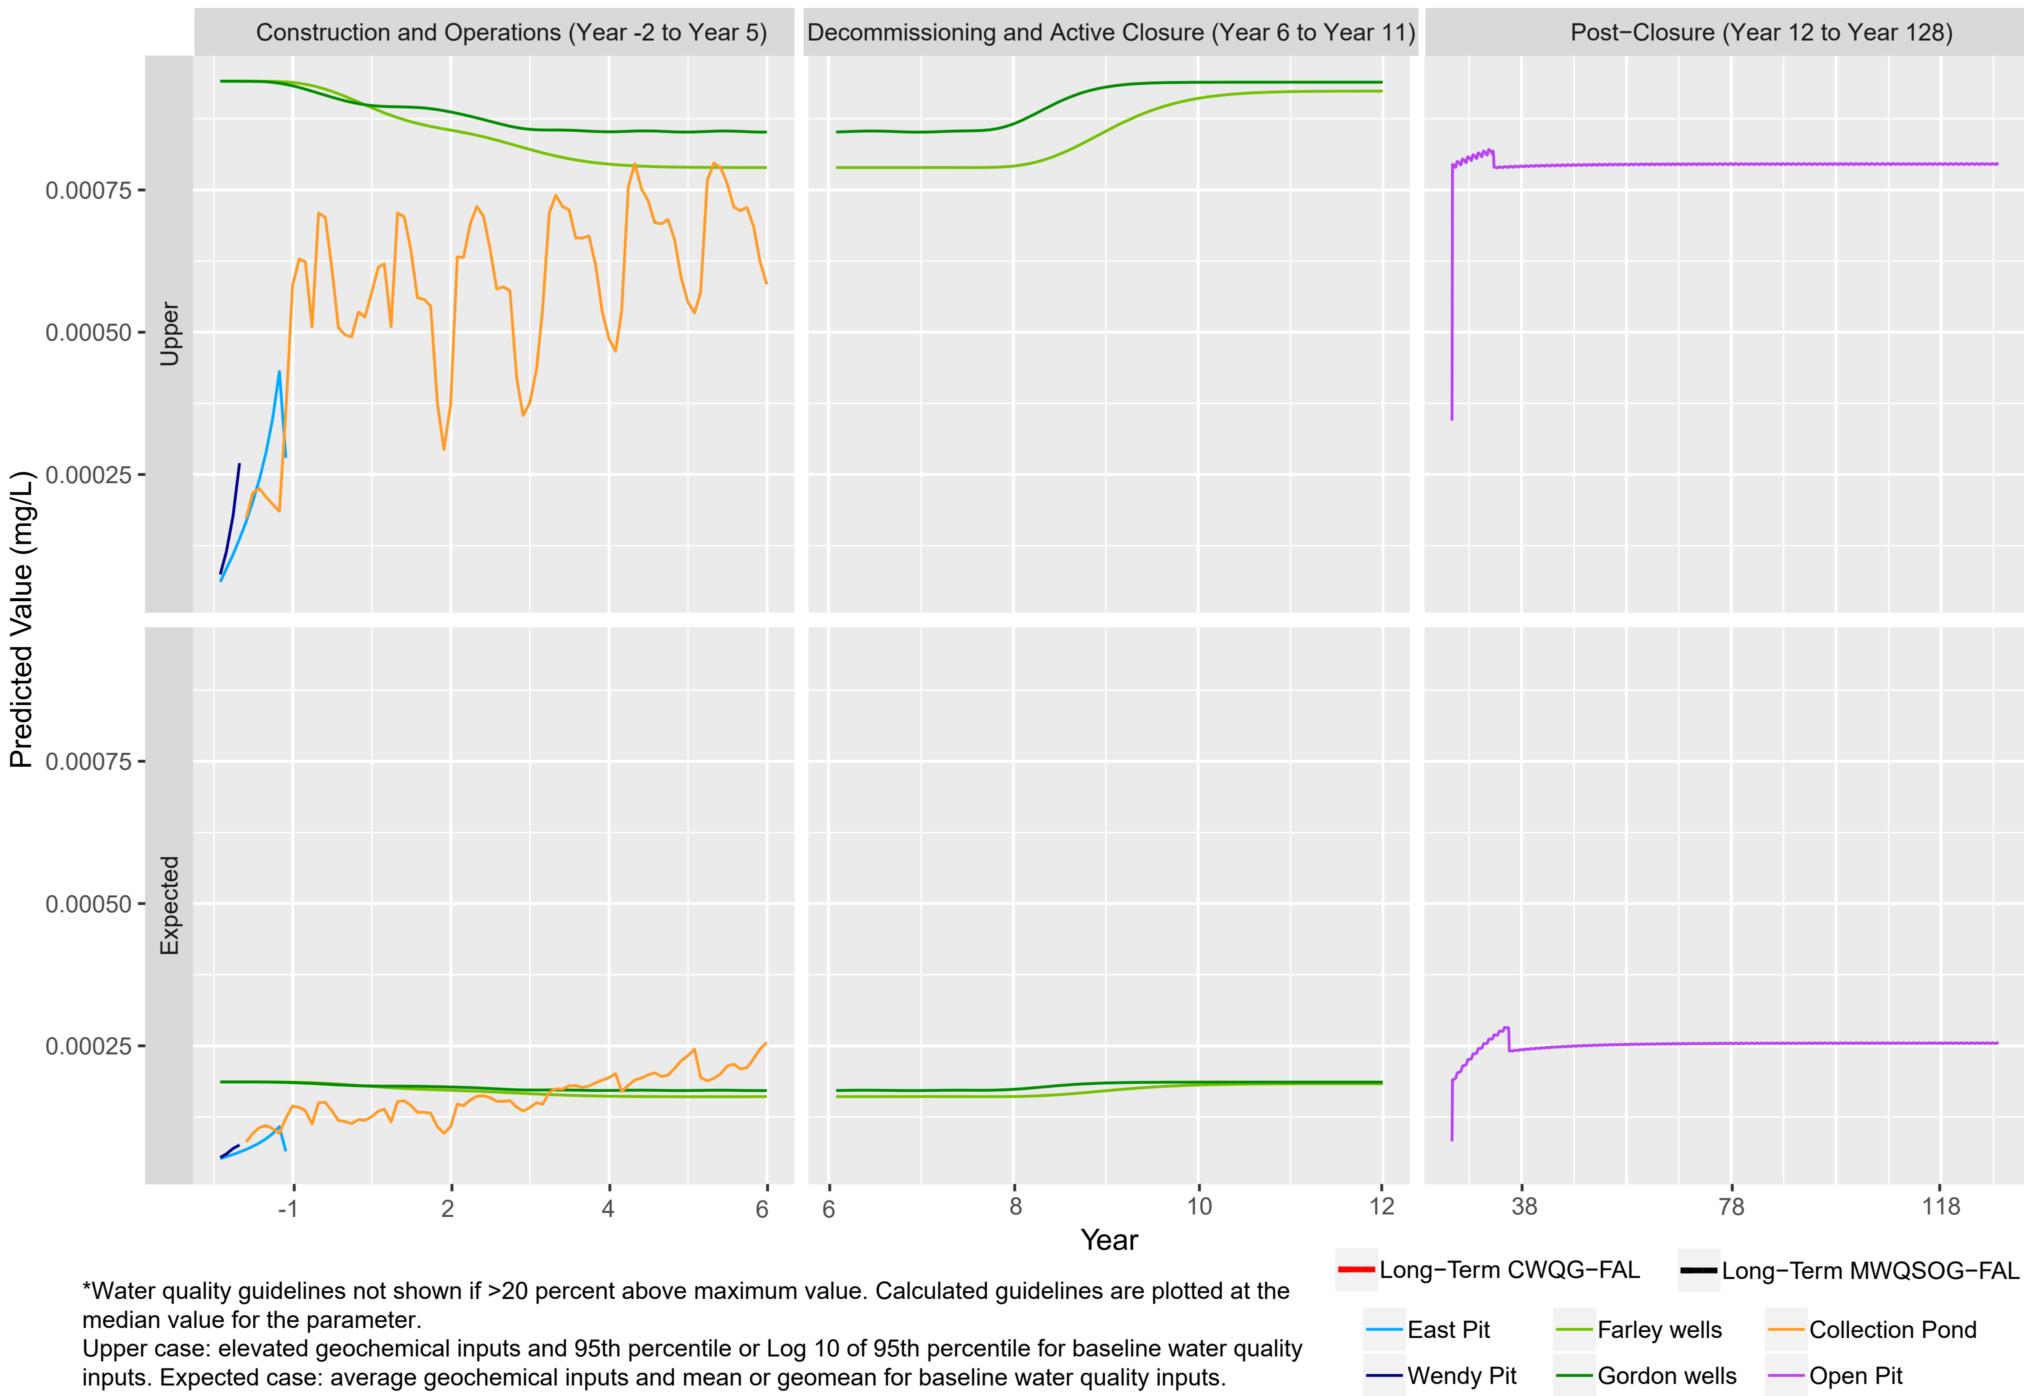
Chromium (Hexavalent), (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

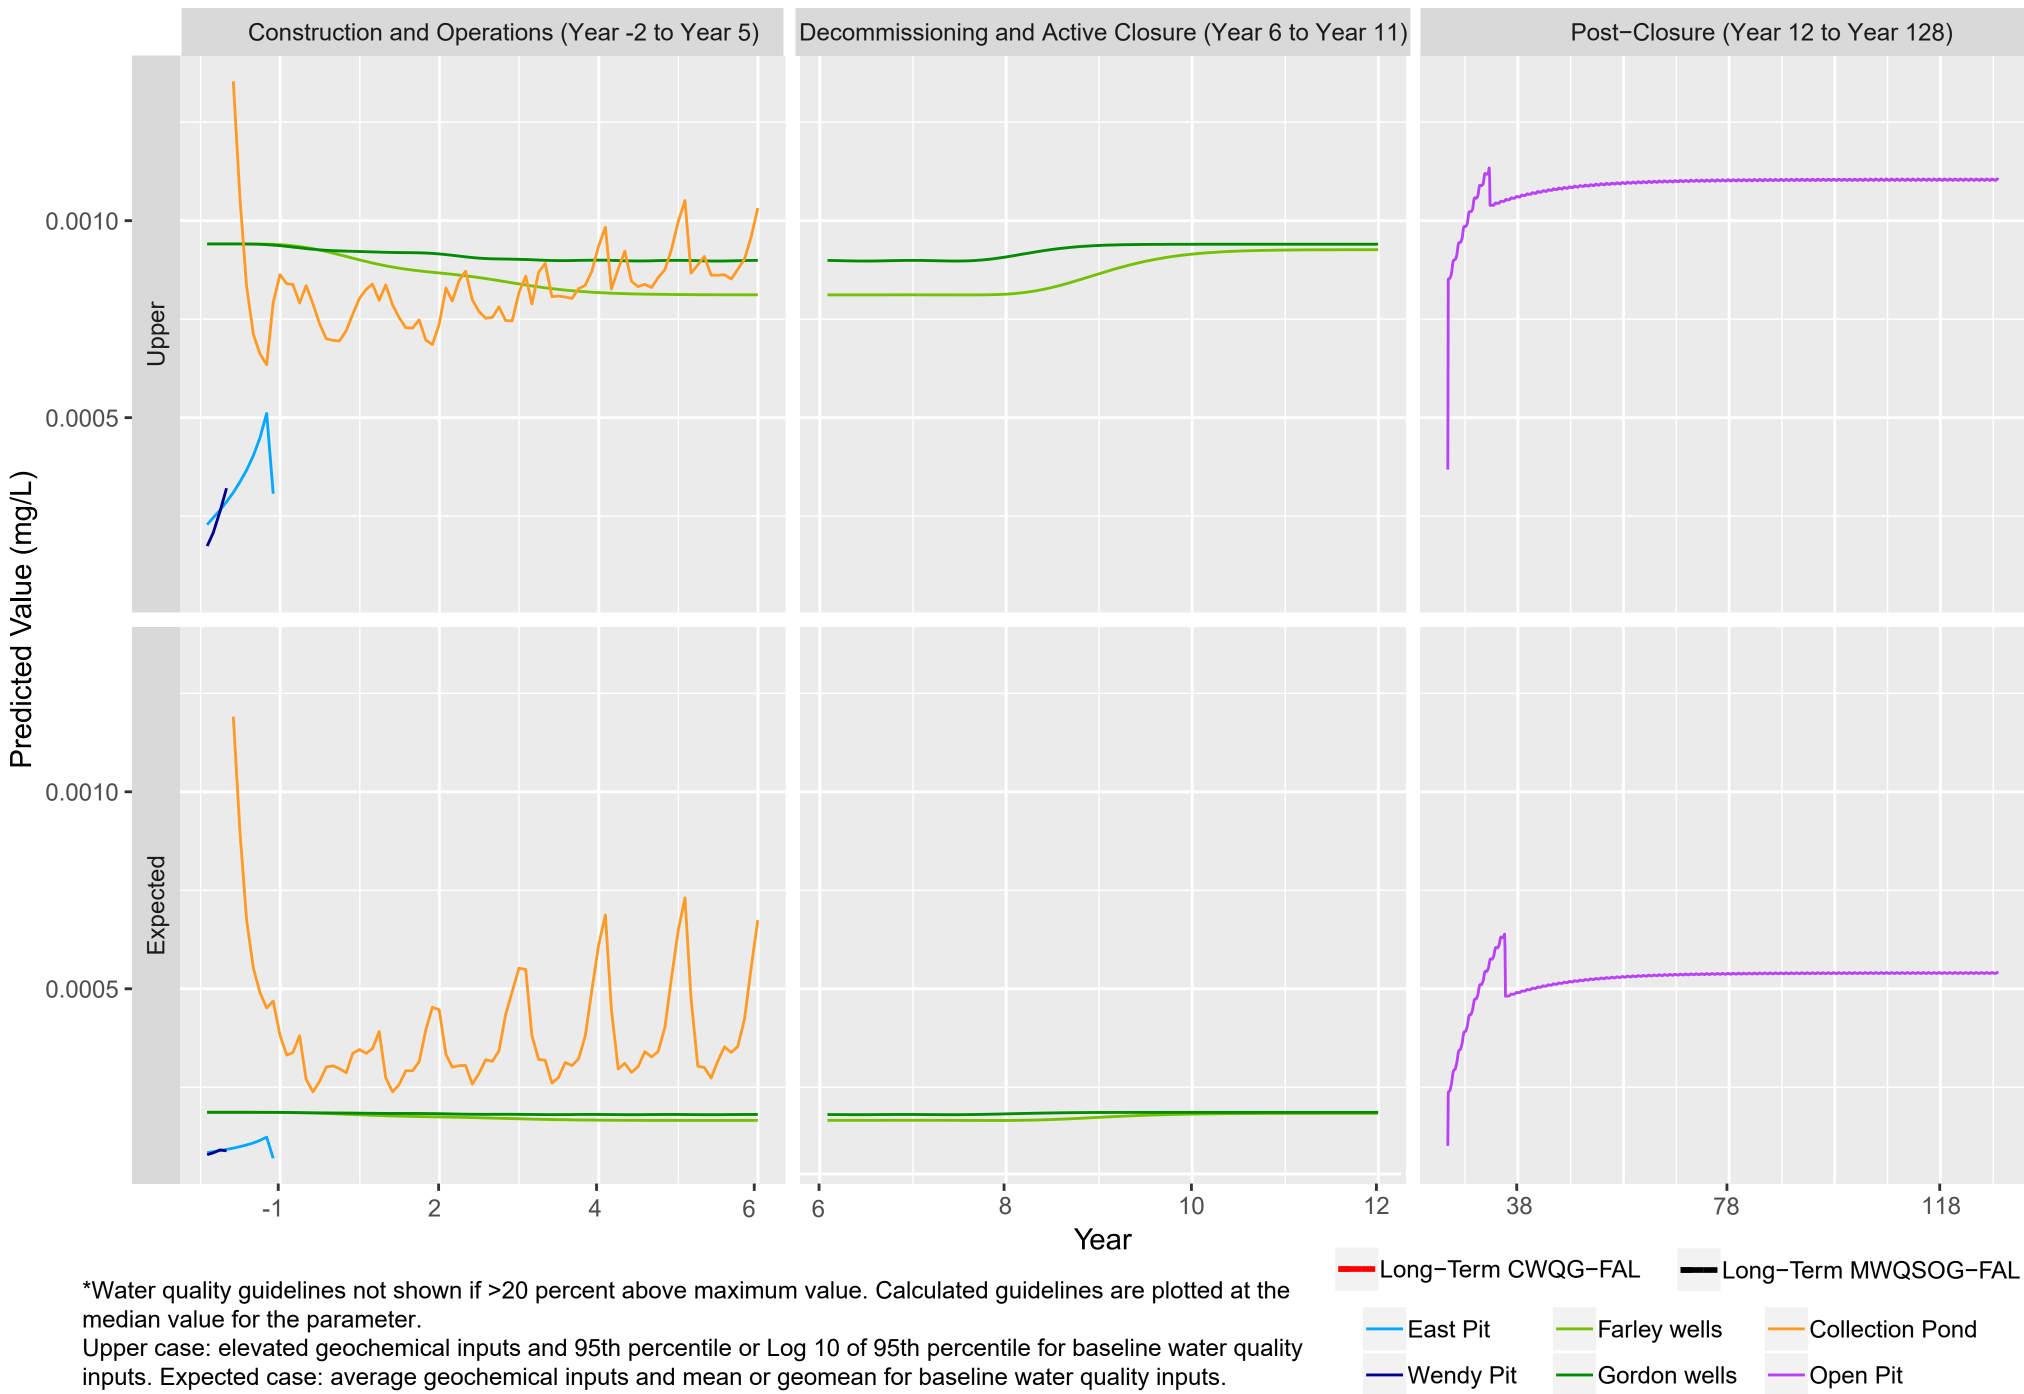
Chromium, Dissolved (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

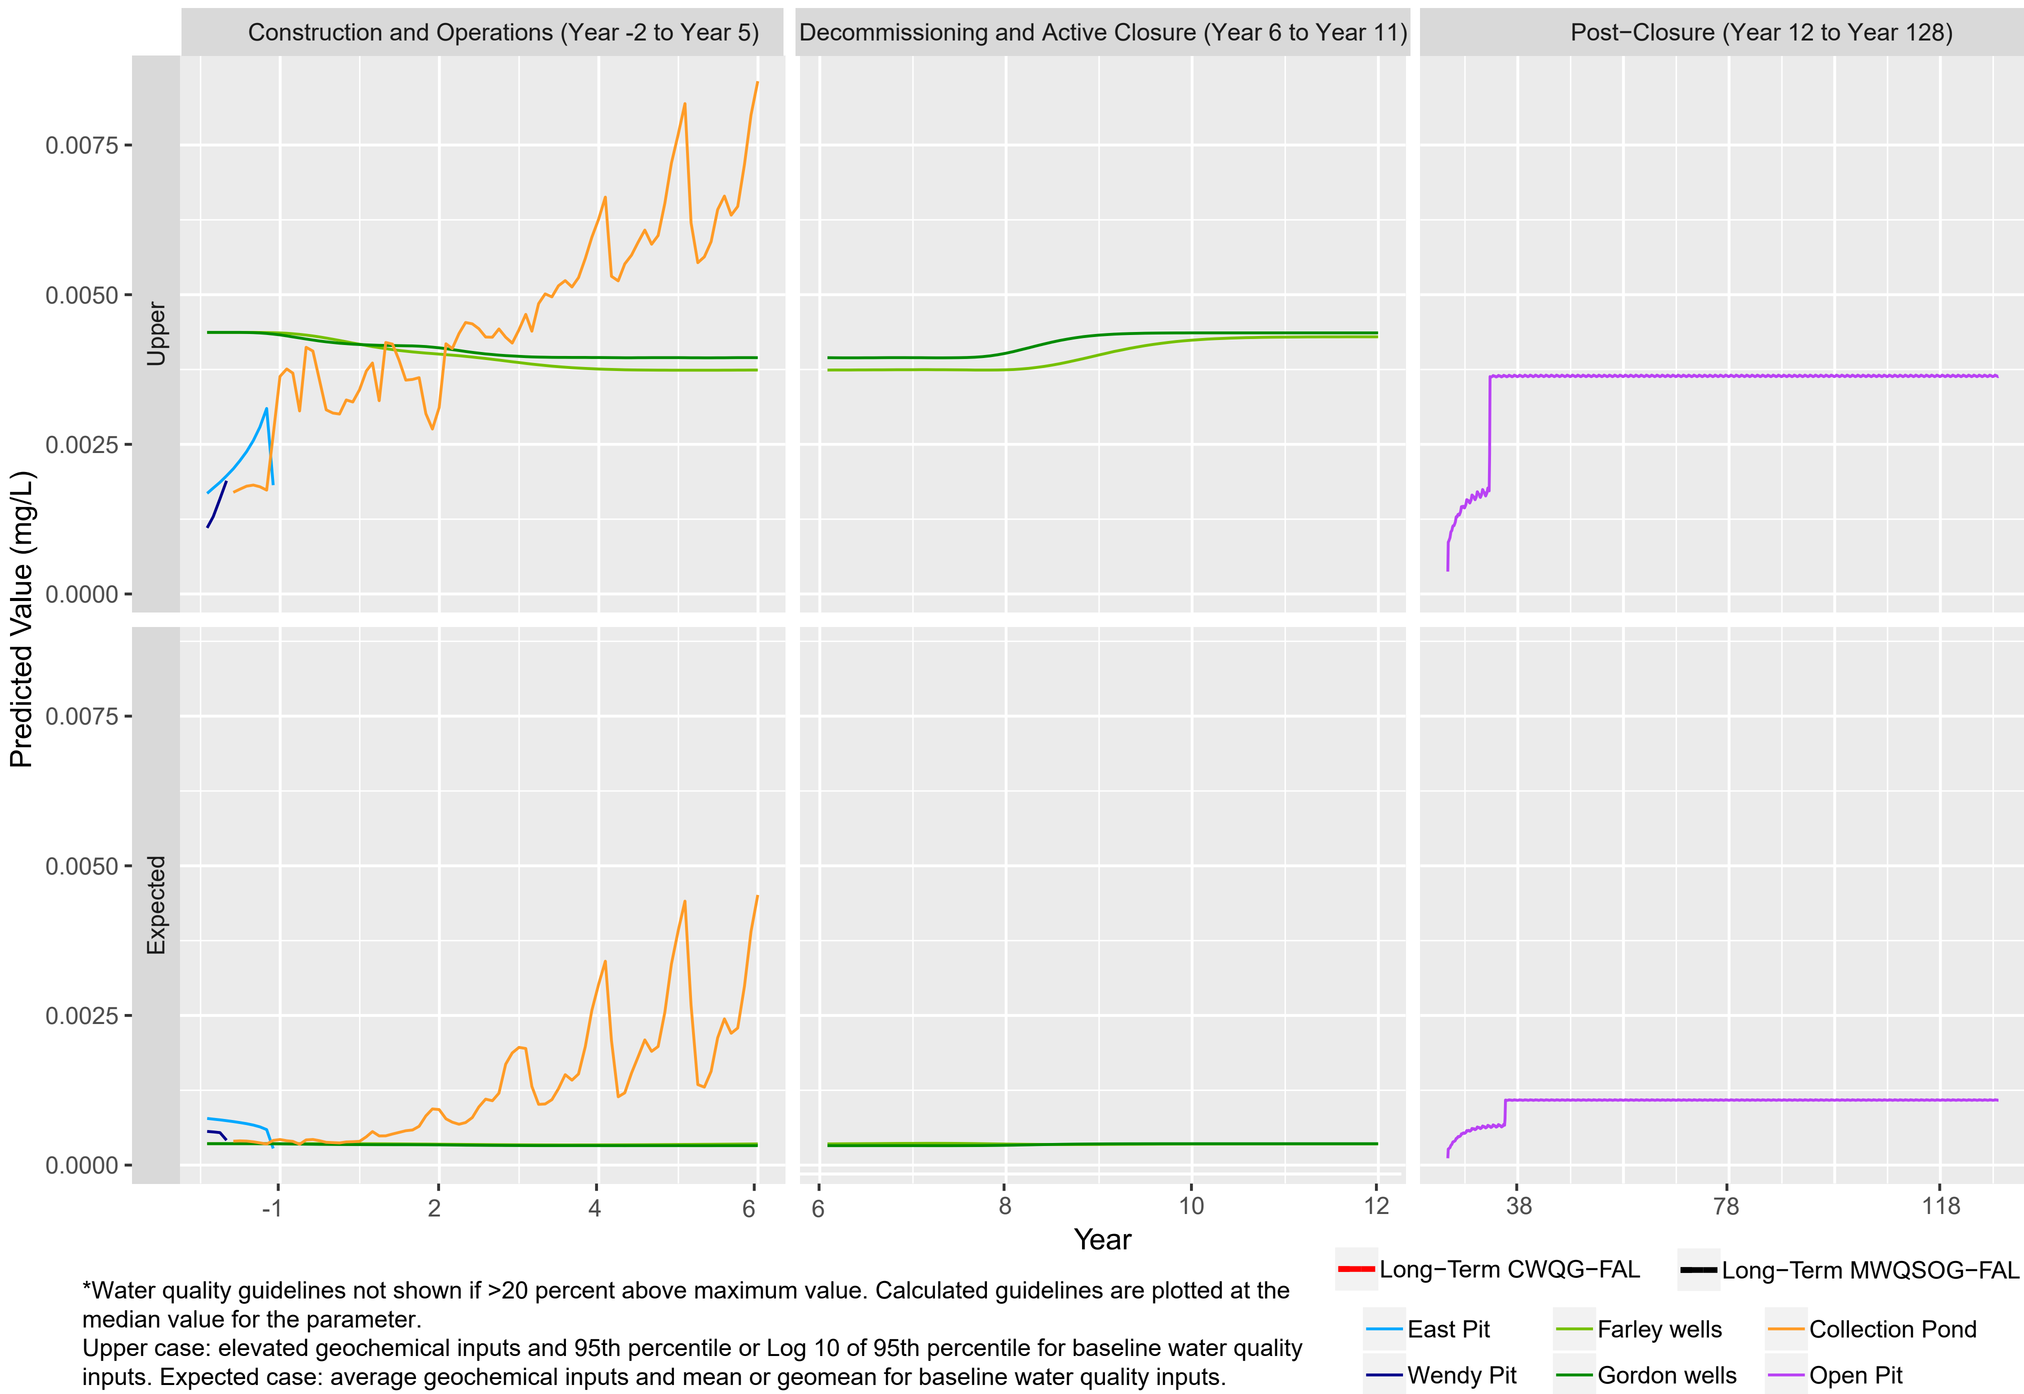
Chromium, Total (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

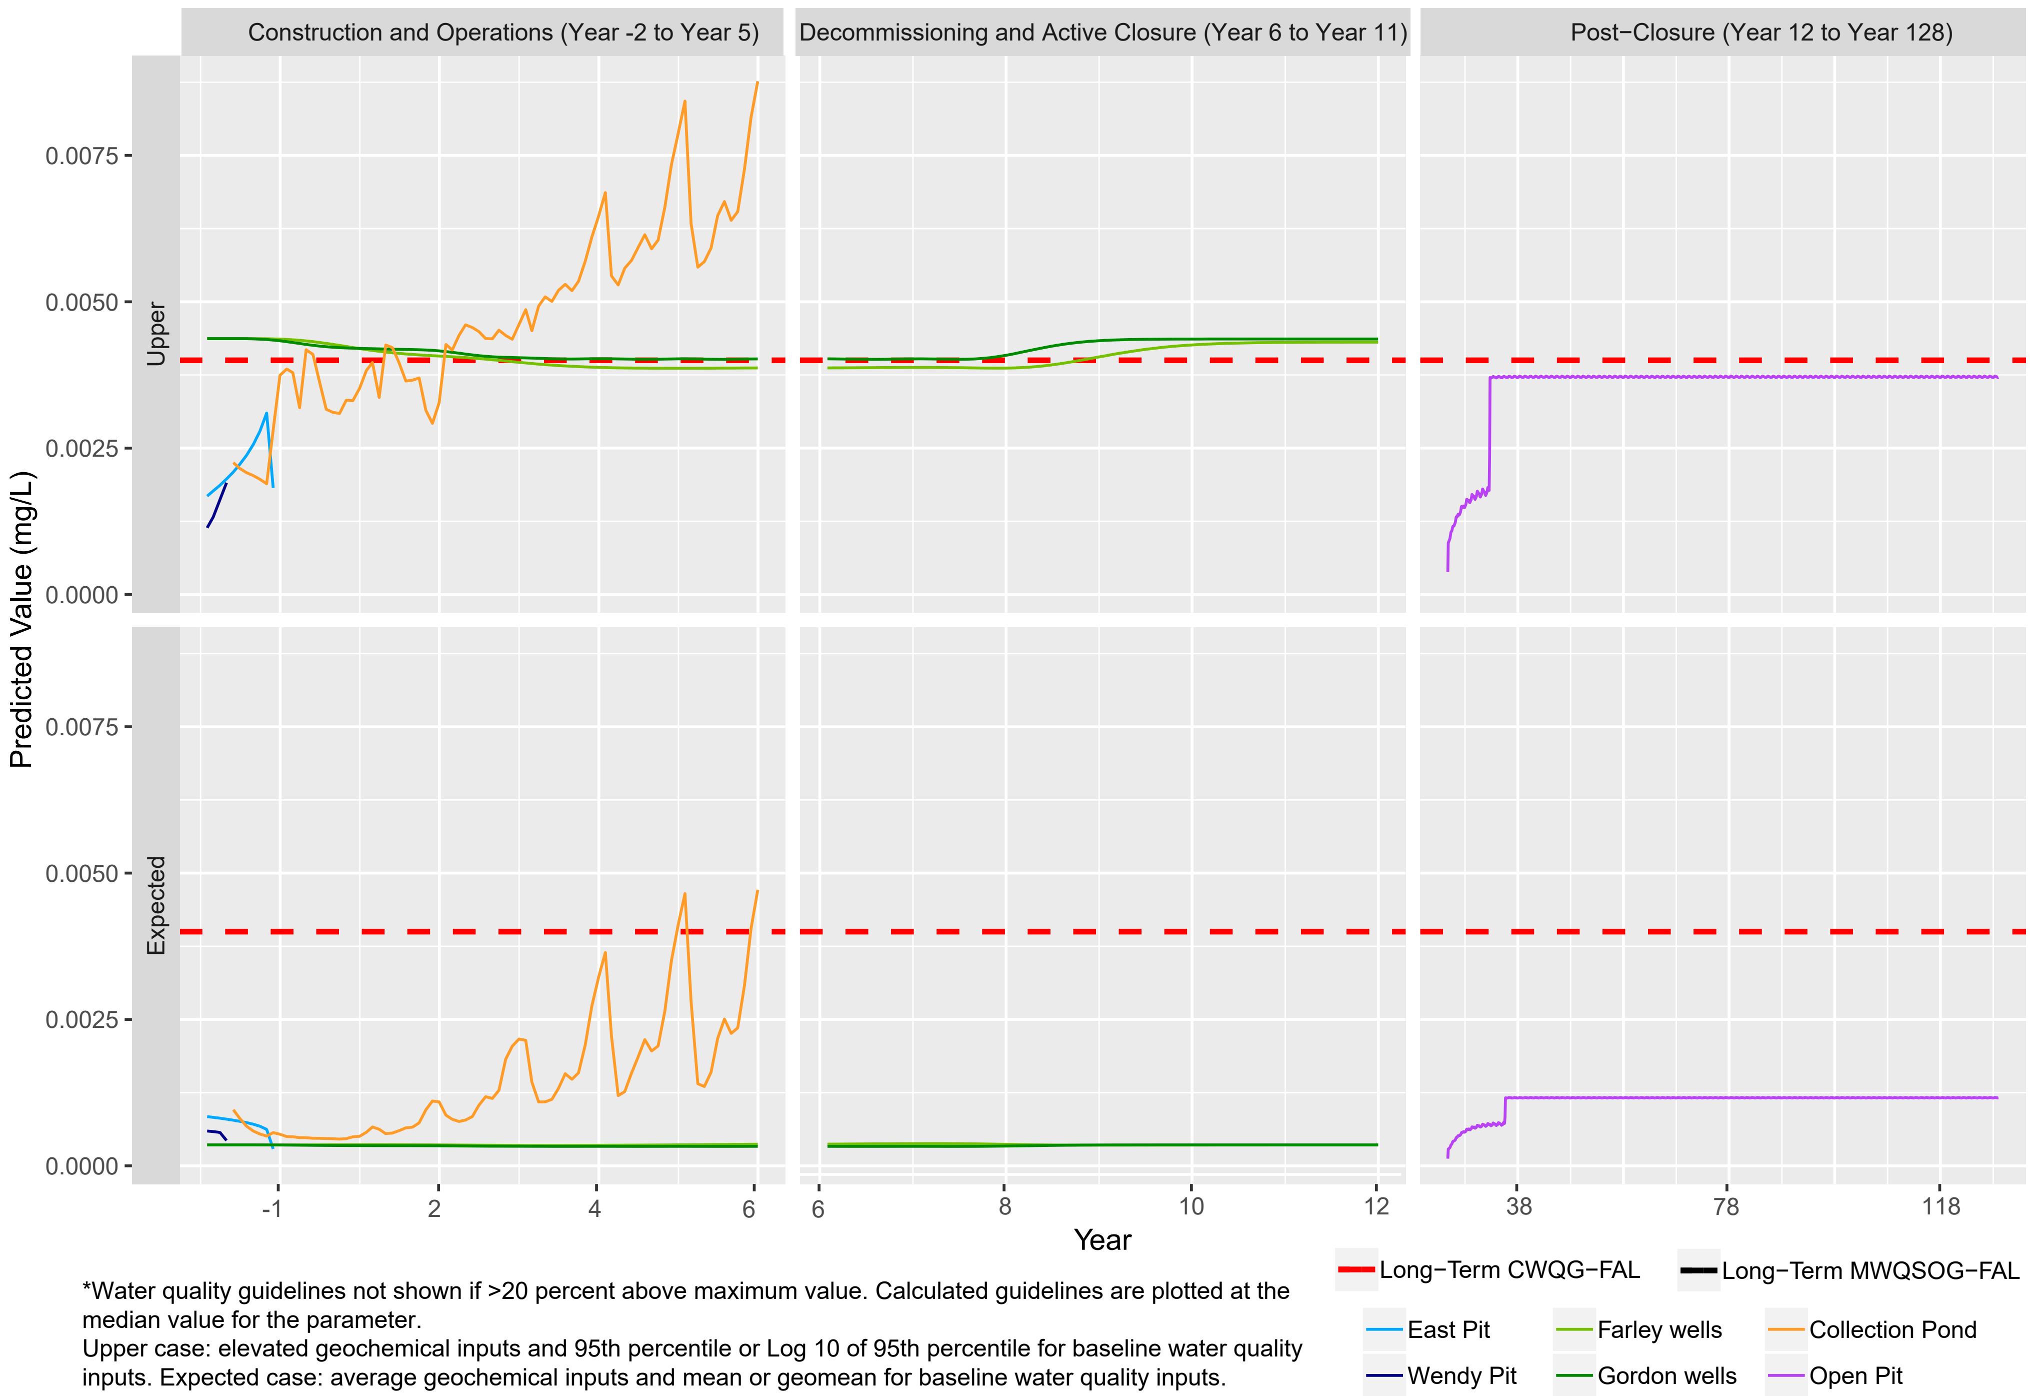
Copper, Dissolved (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

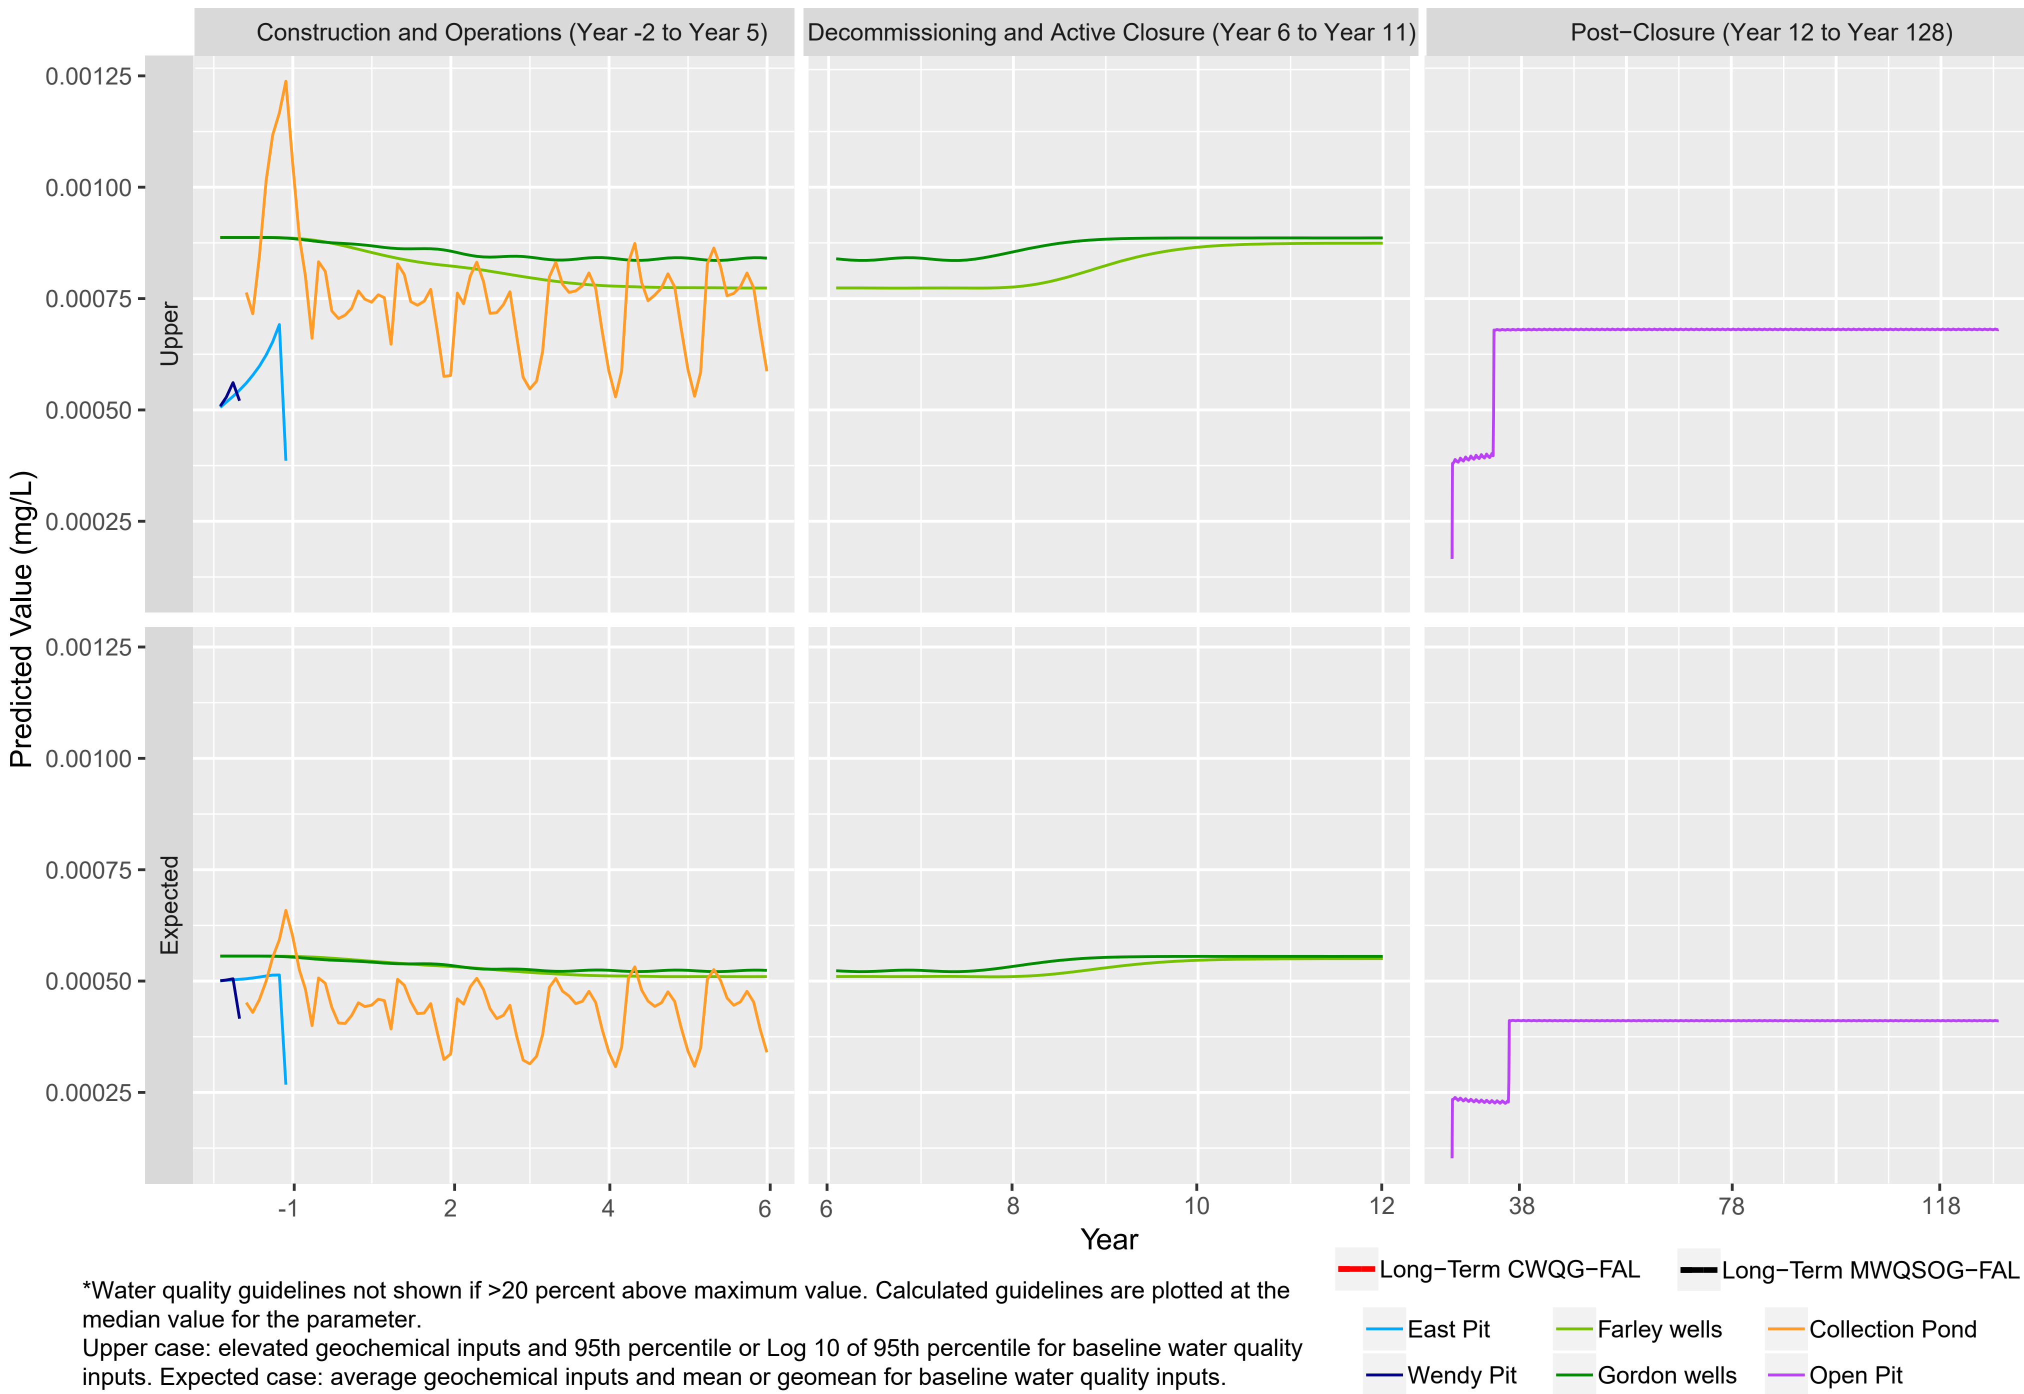
Copper, Total (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

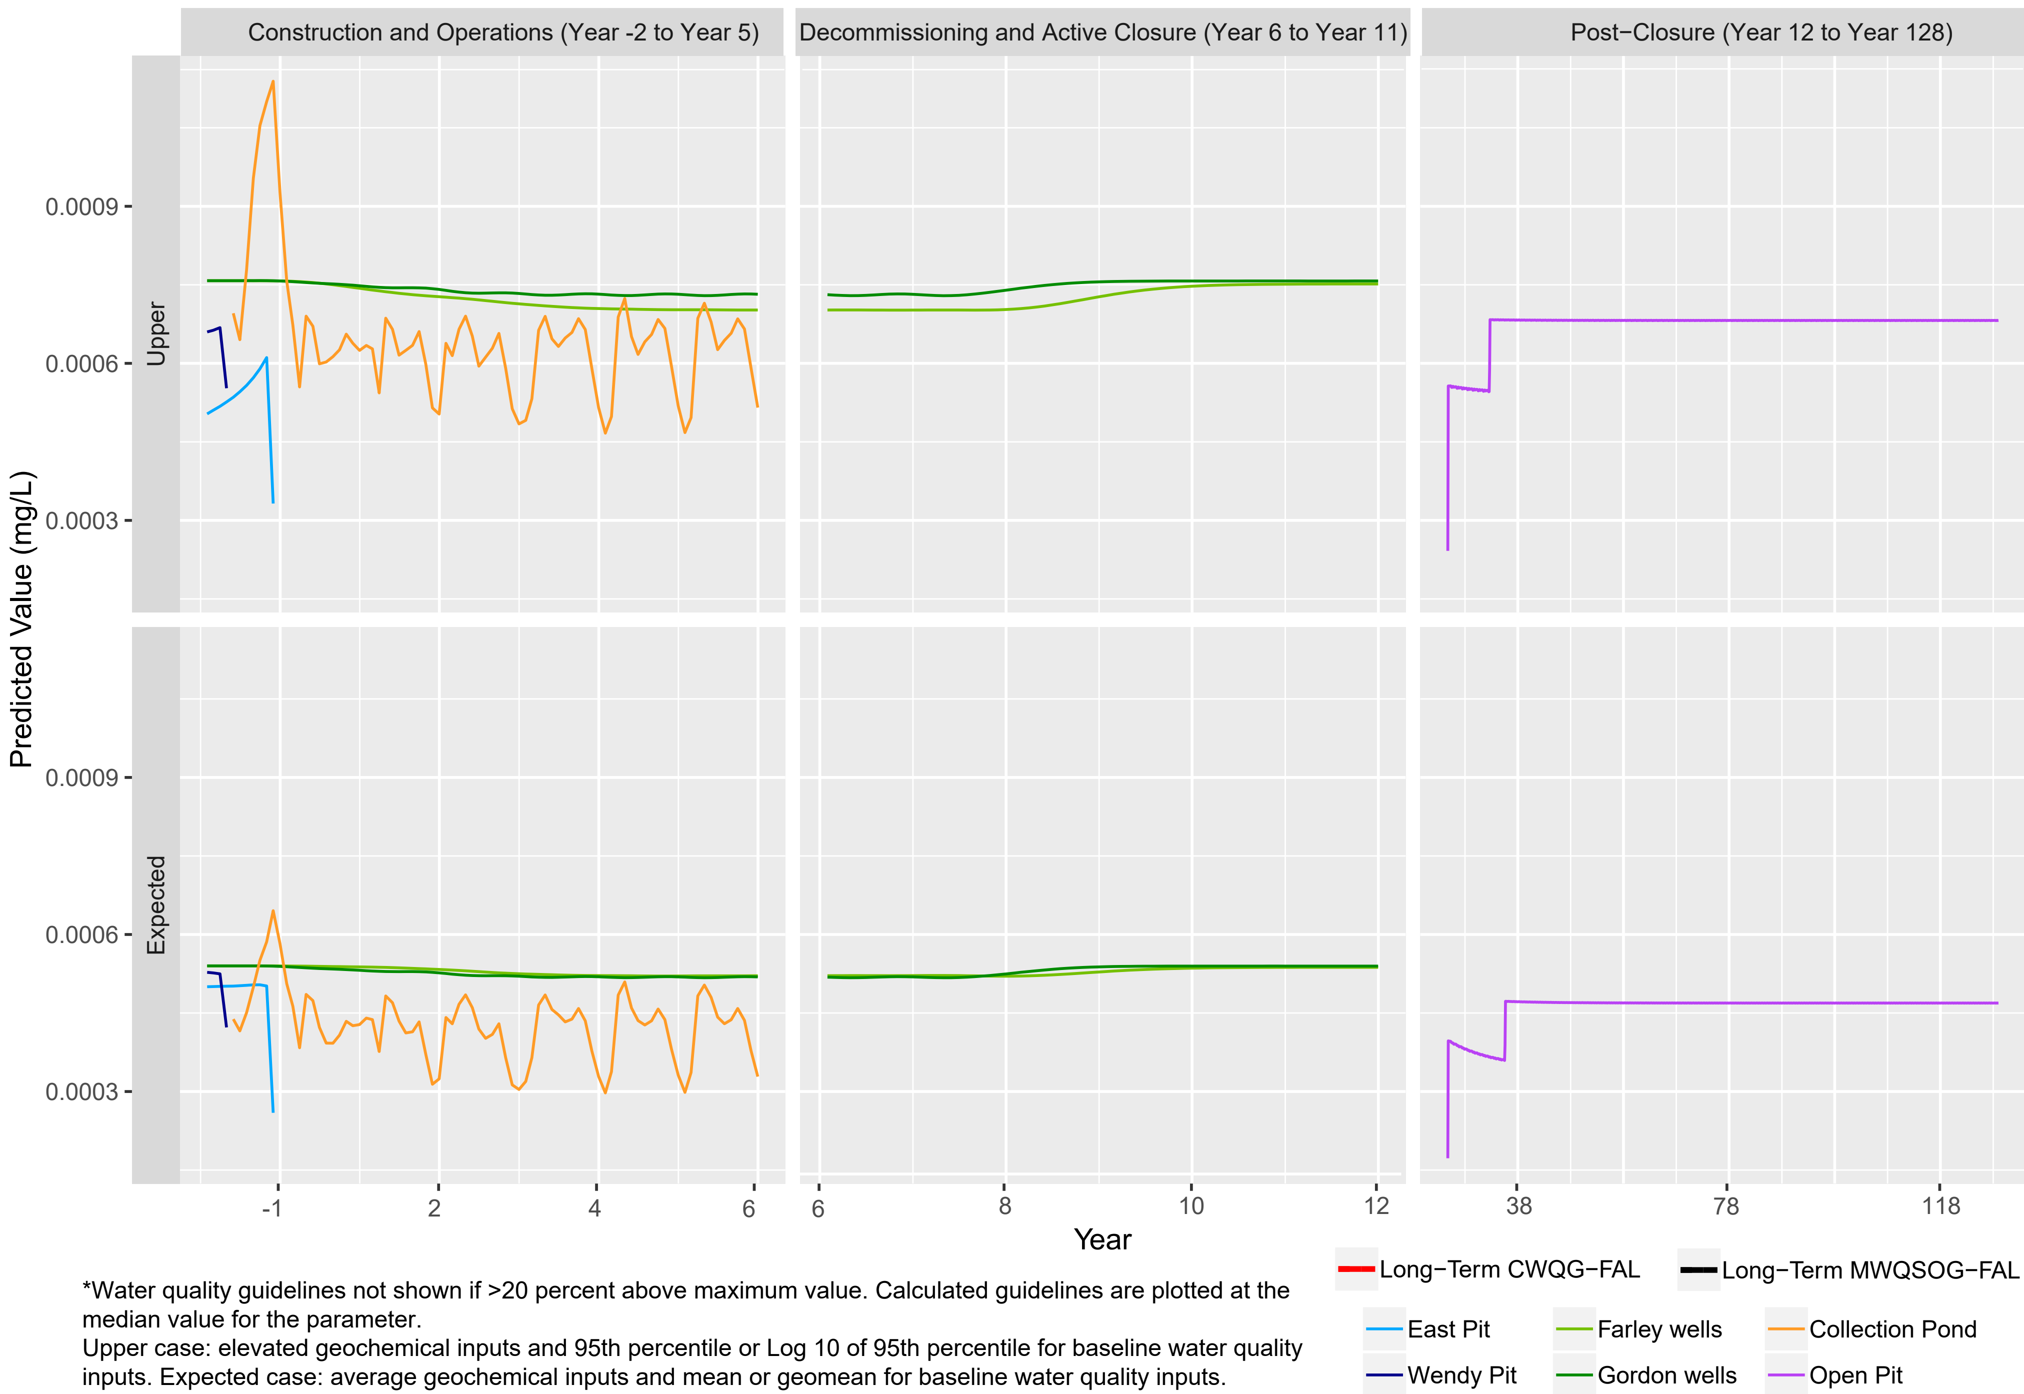
Cyanide (Free), (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

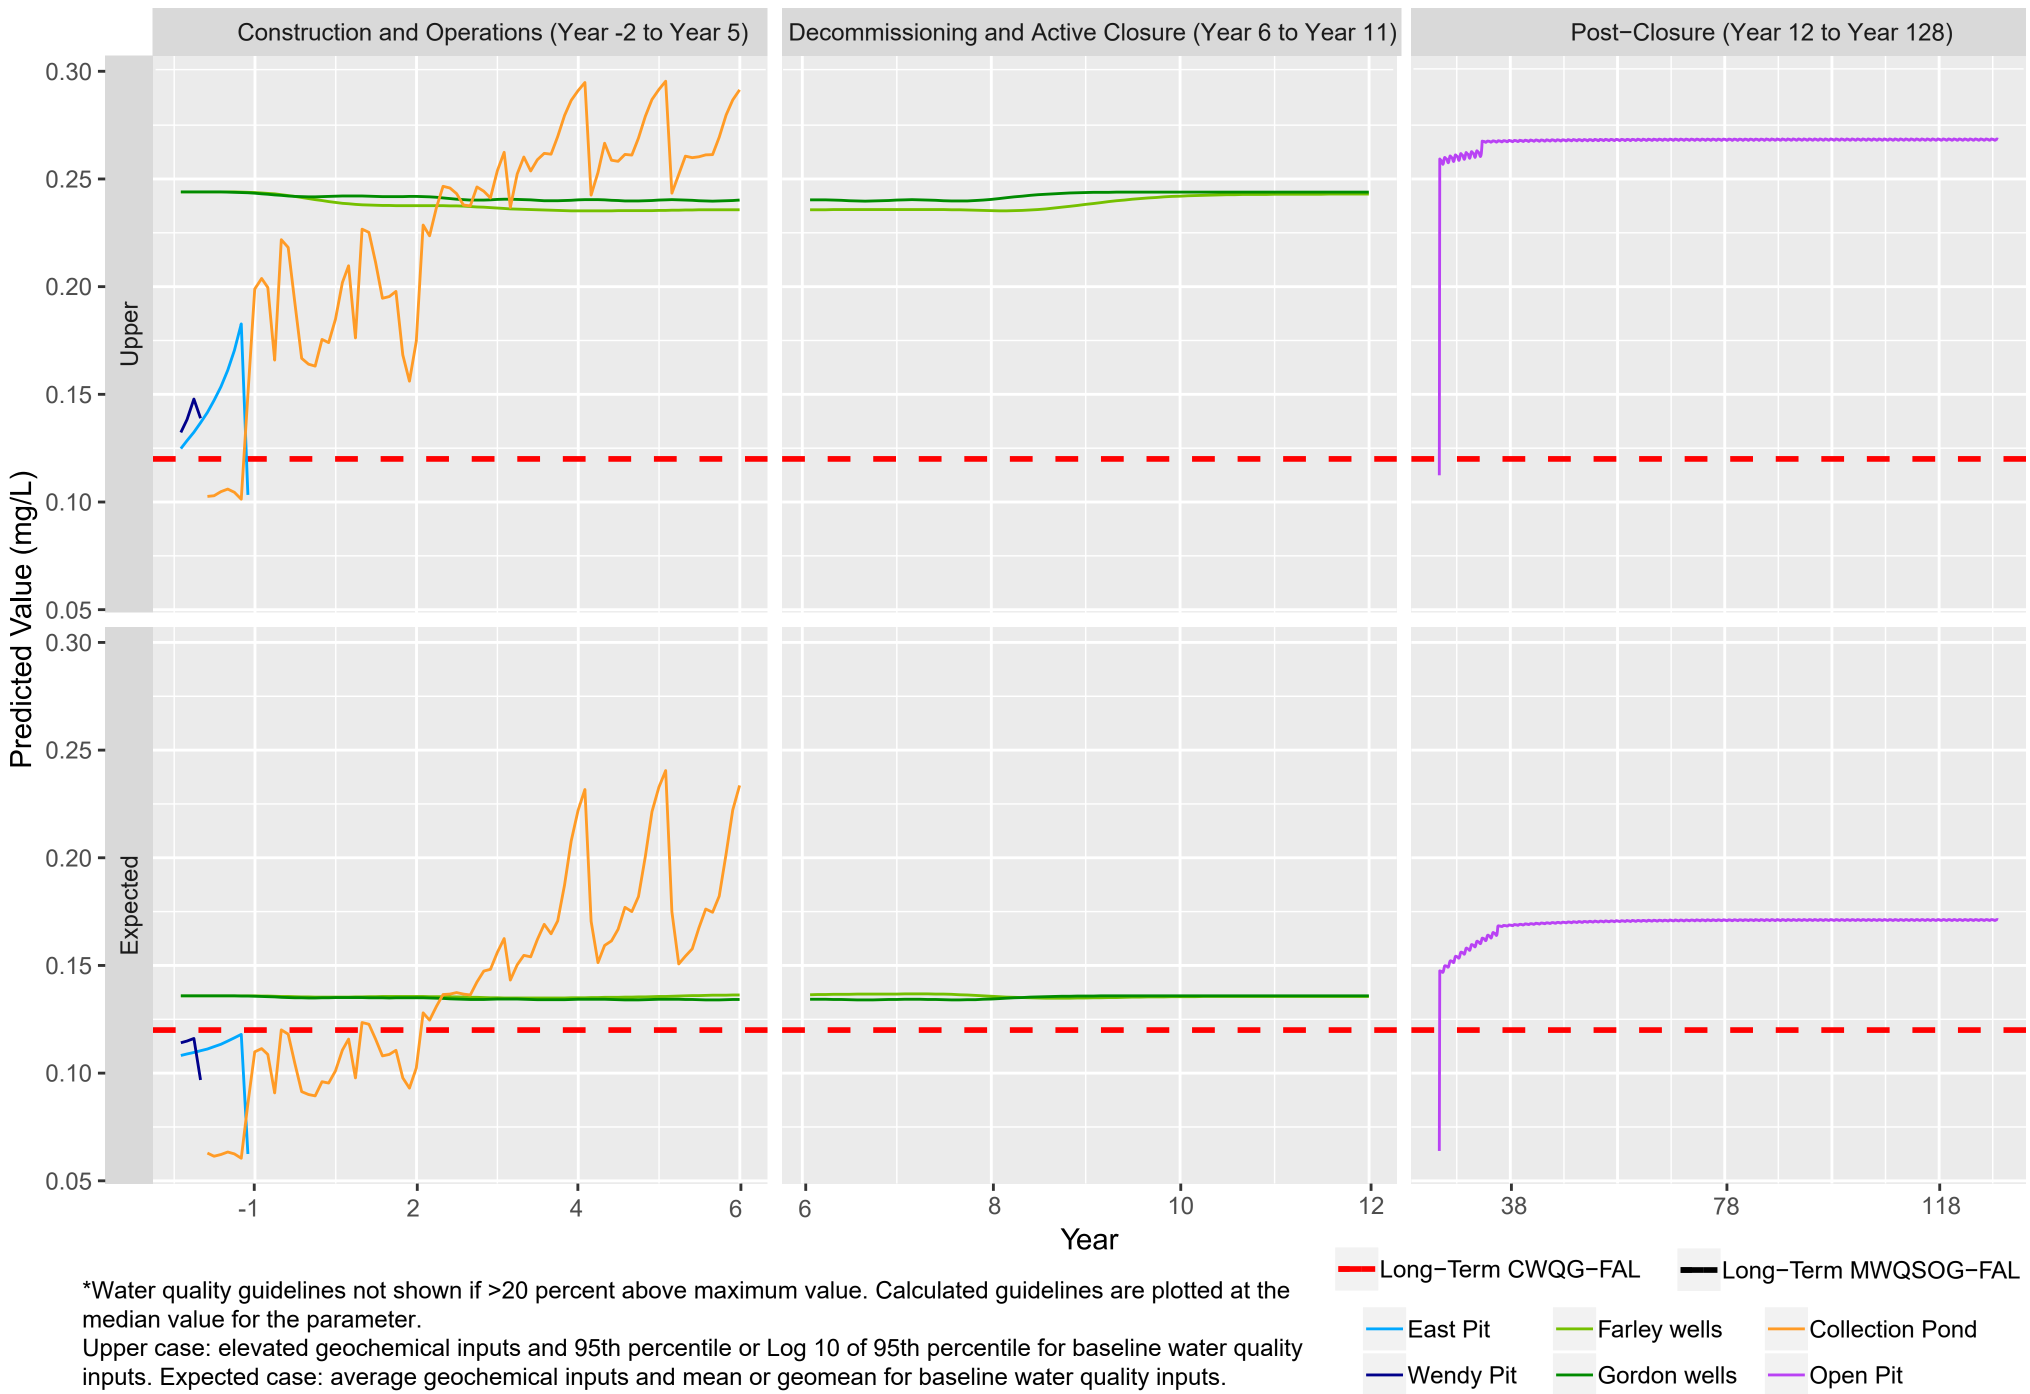
Cyanide, Total (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

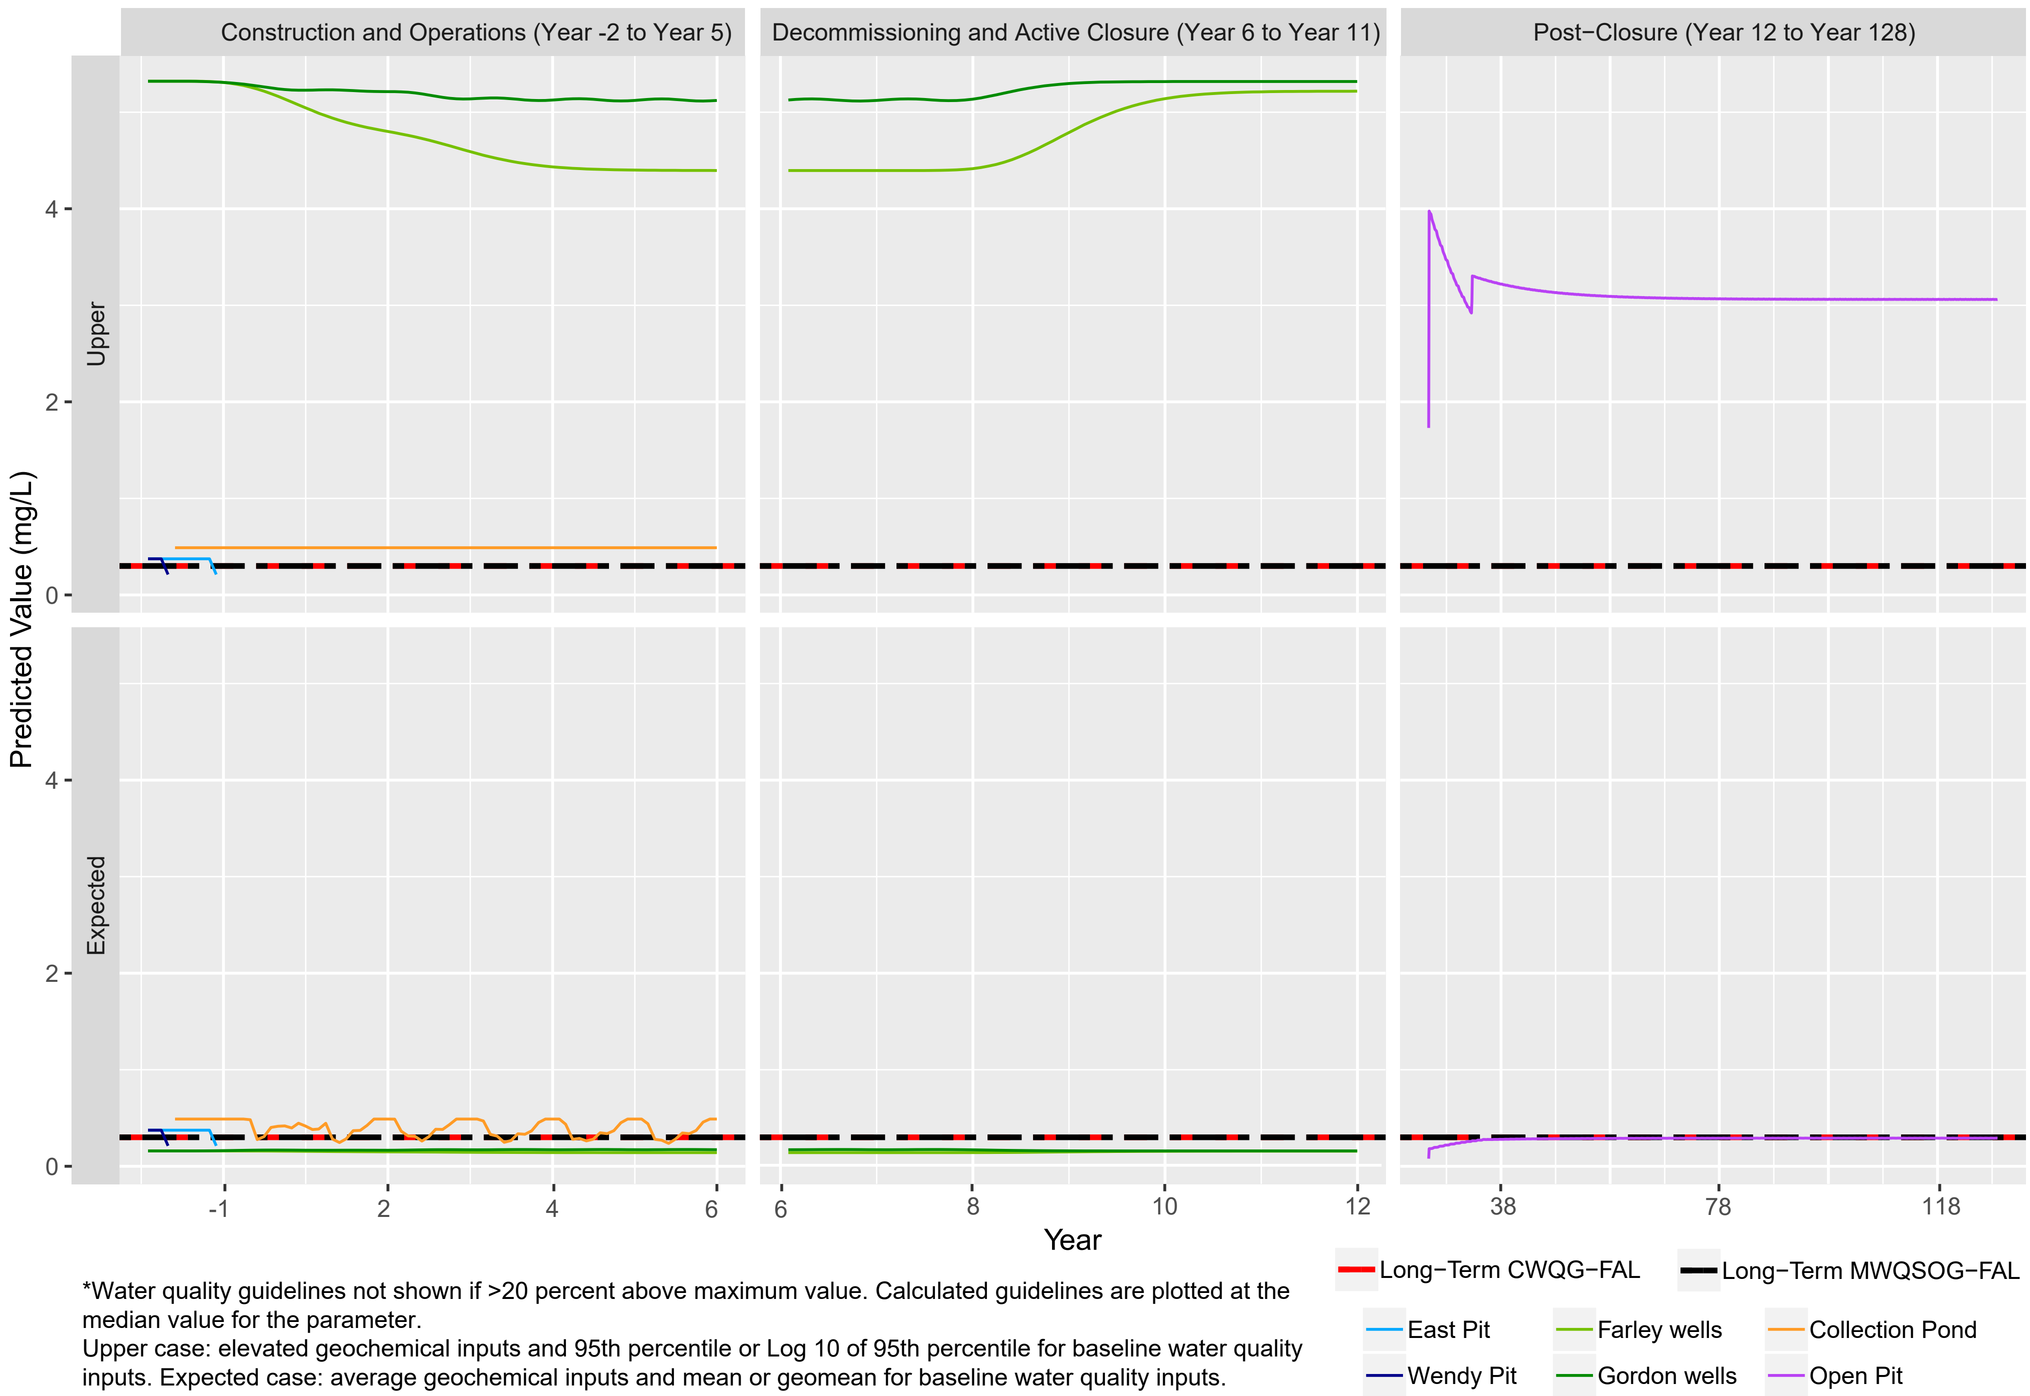
Fluoride, (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

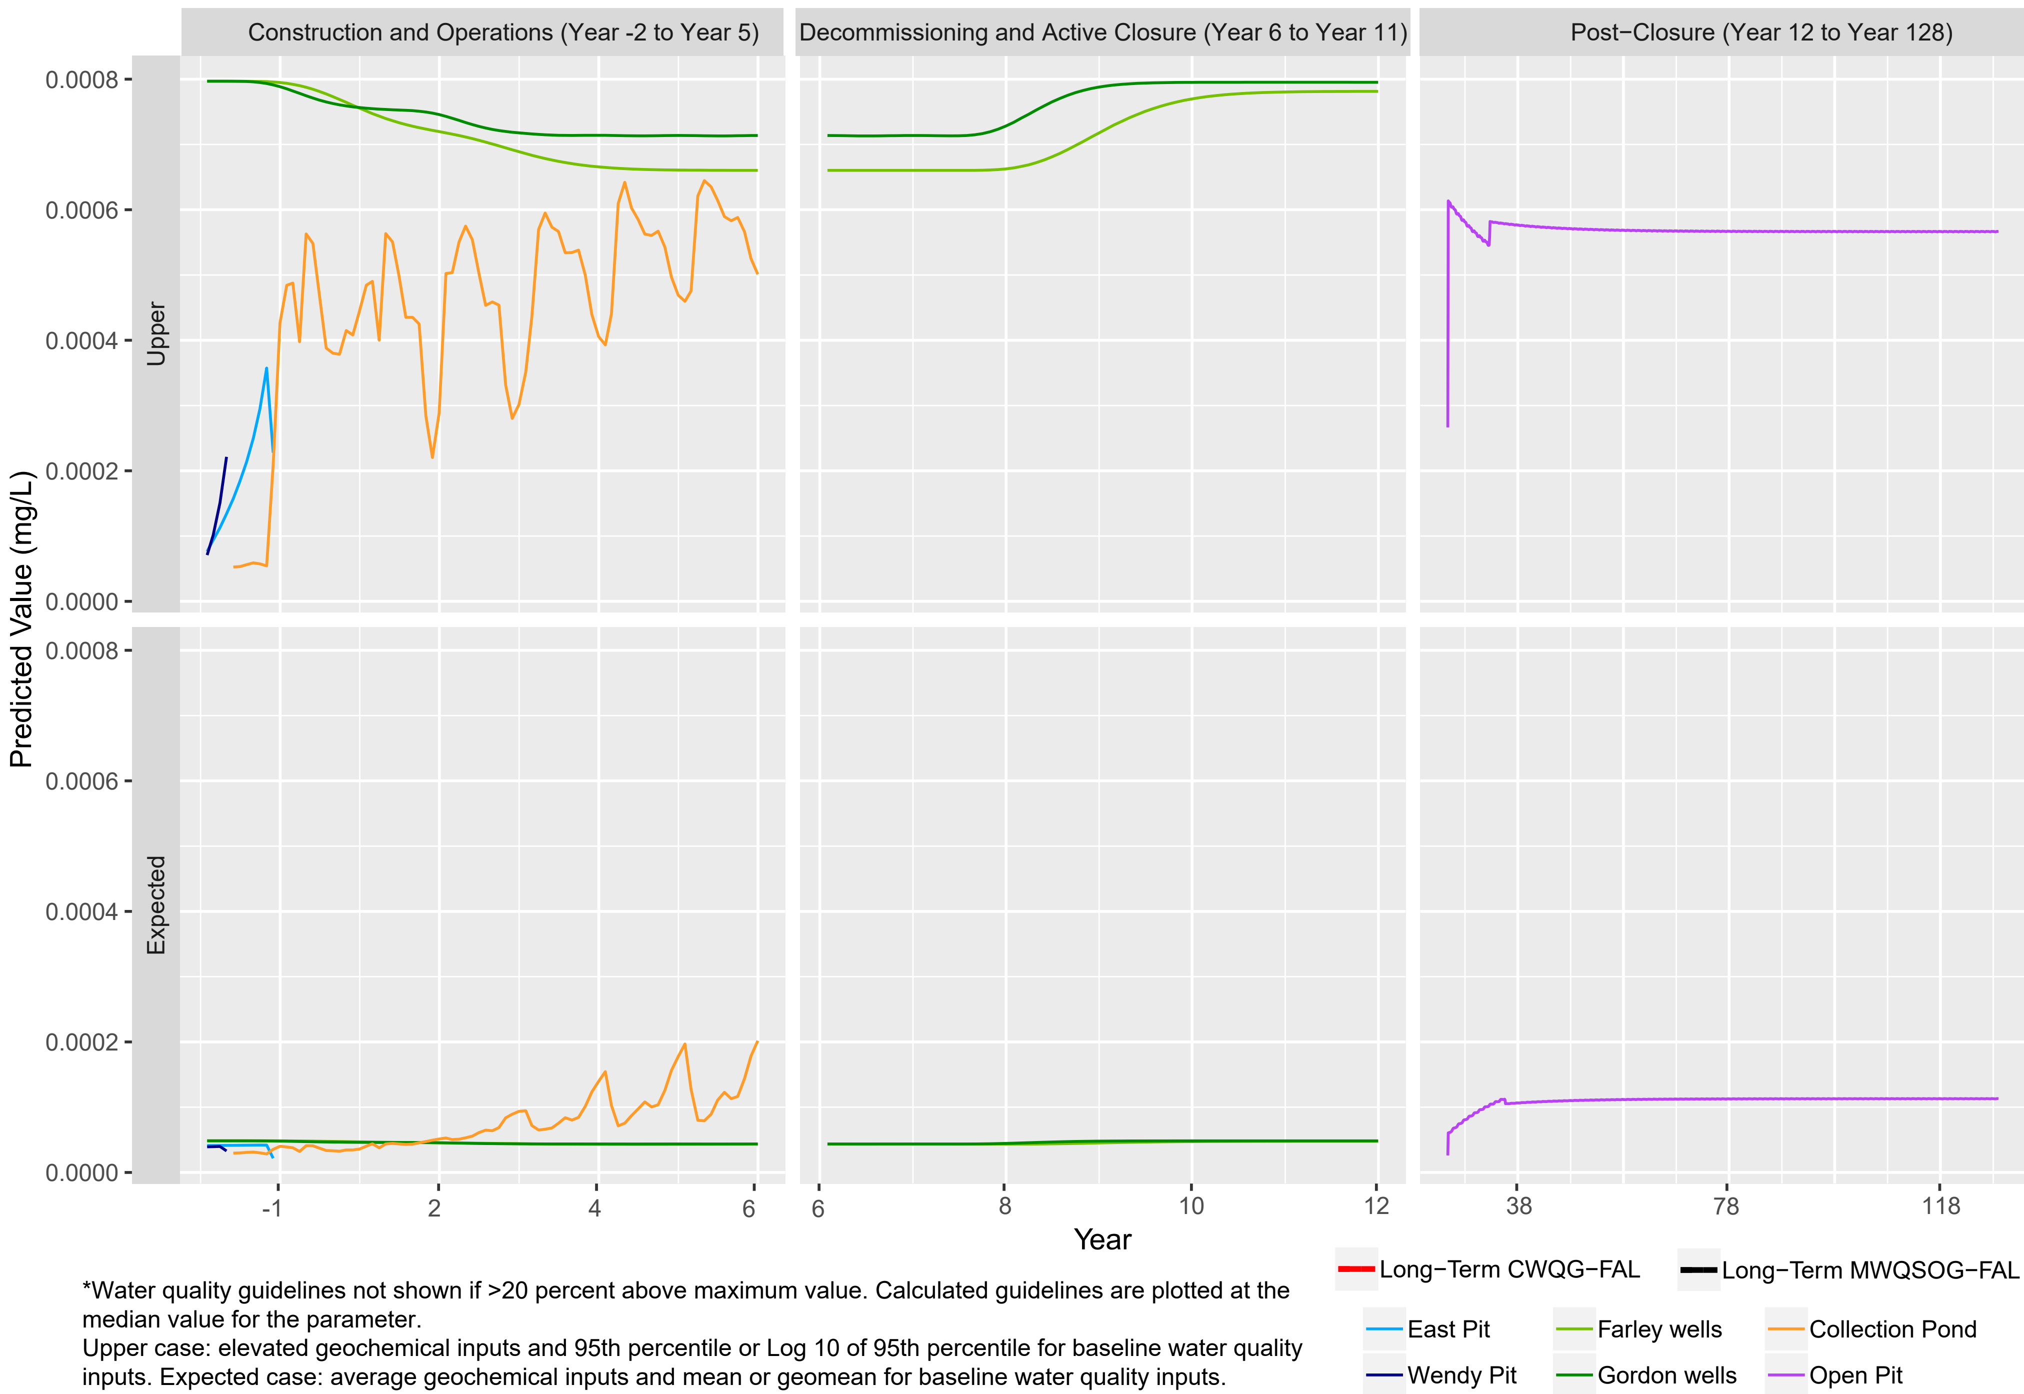
Iron, Total (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

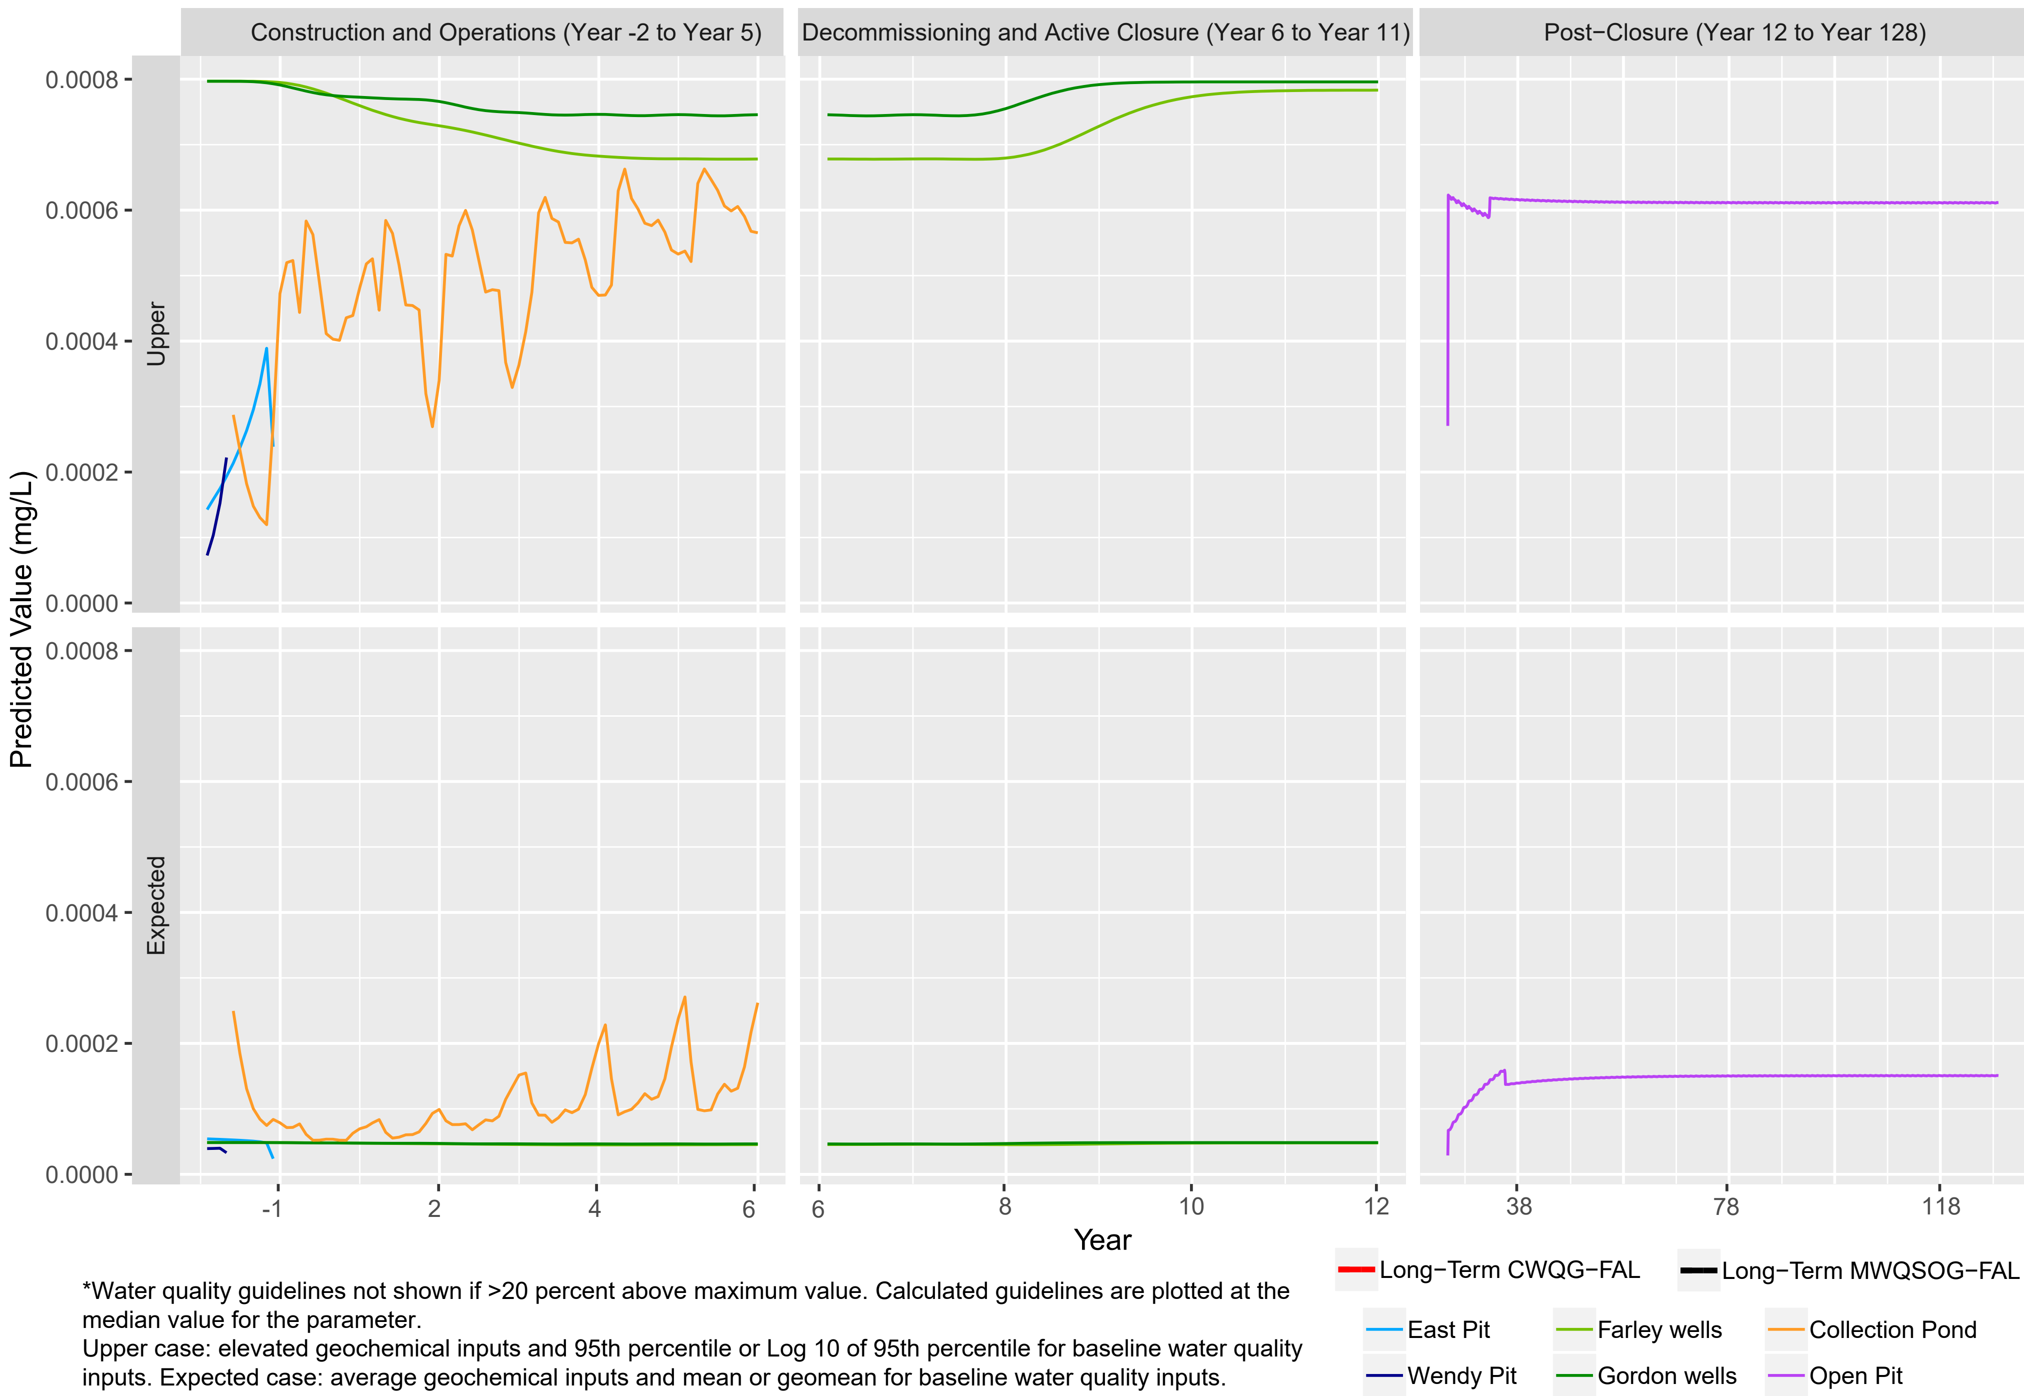
Lead, Dissolved (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

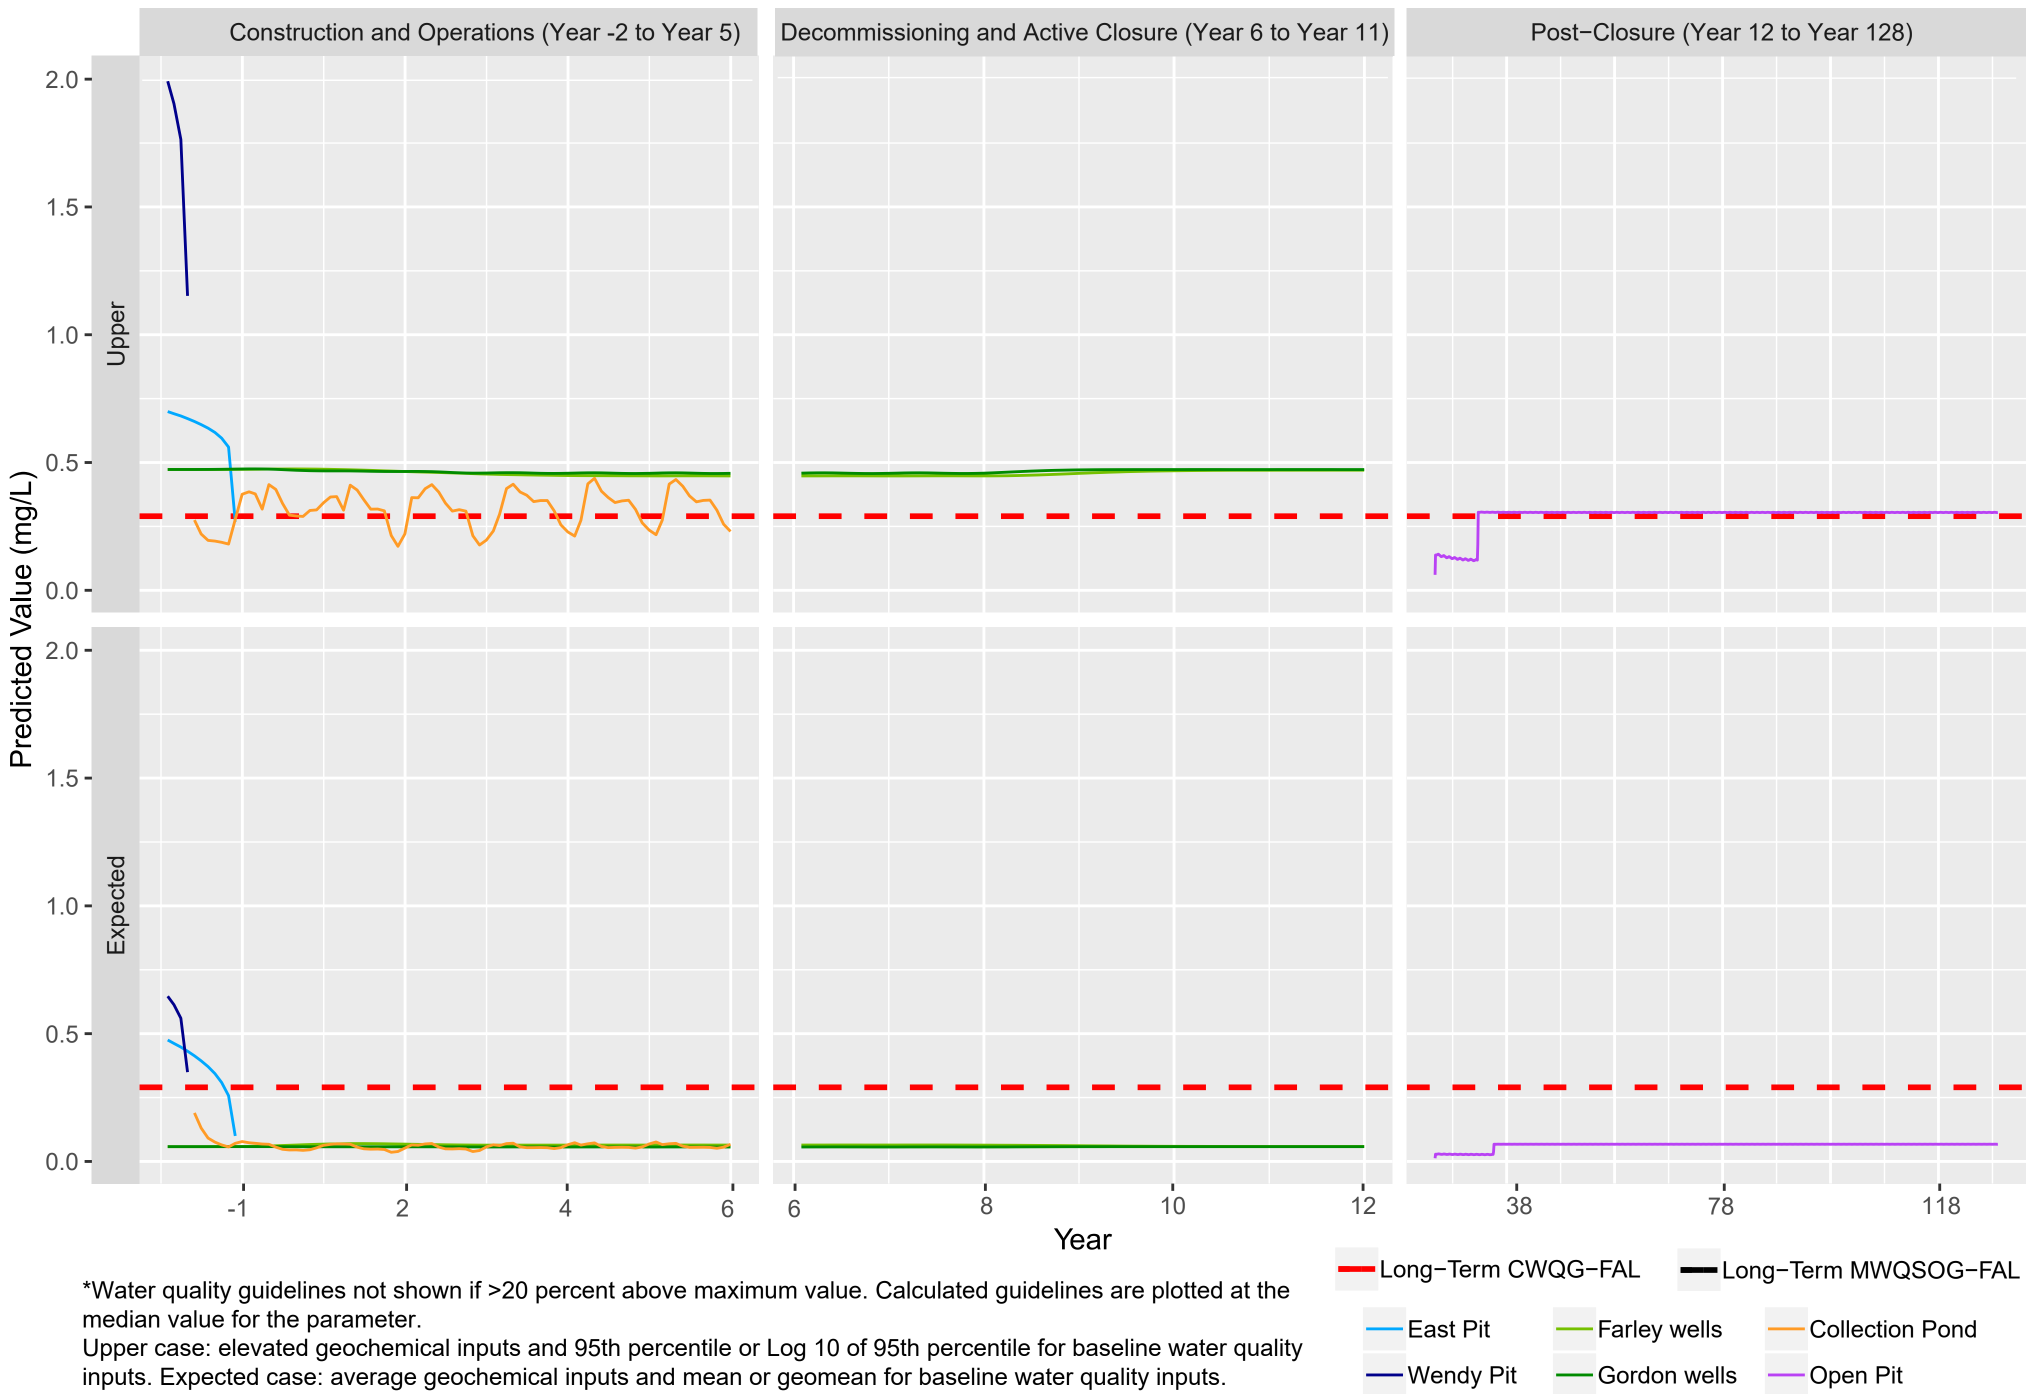
Lead, Total (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

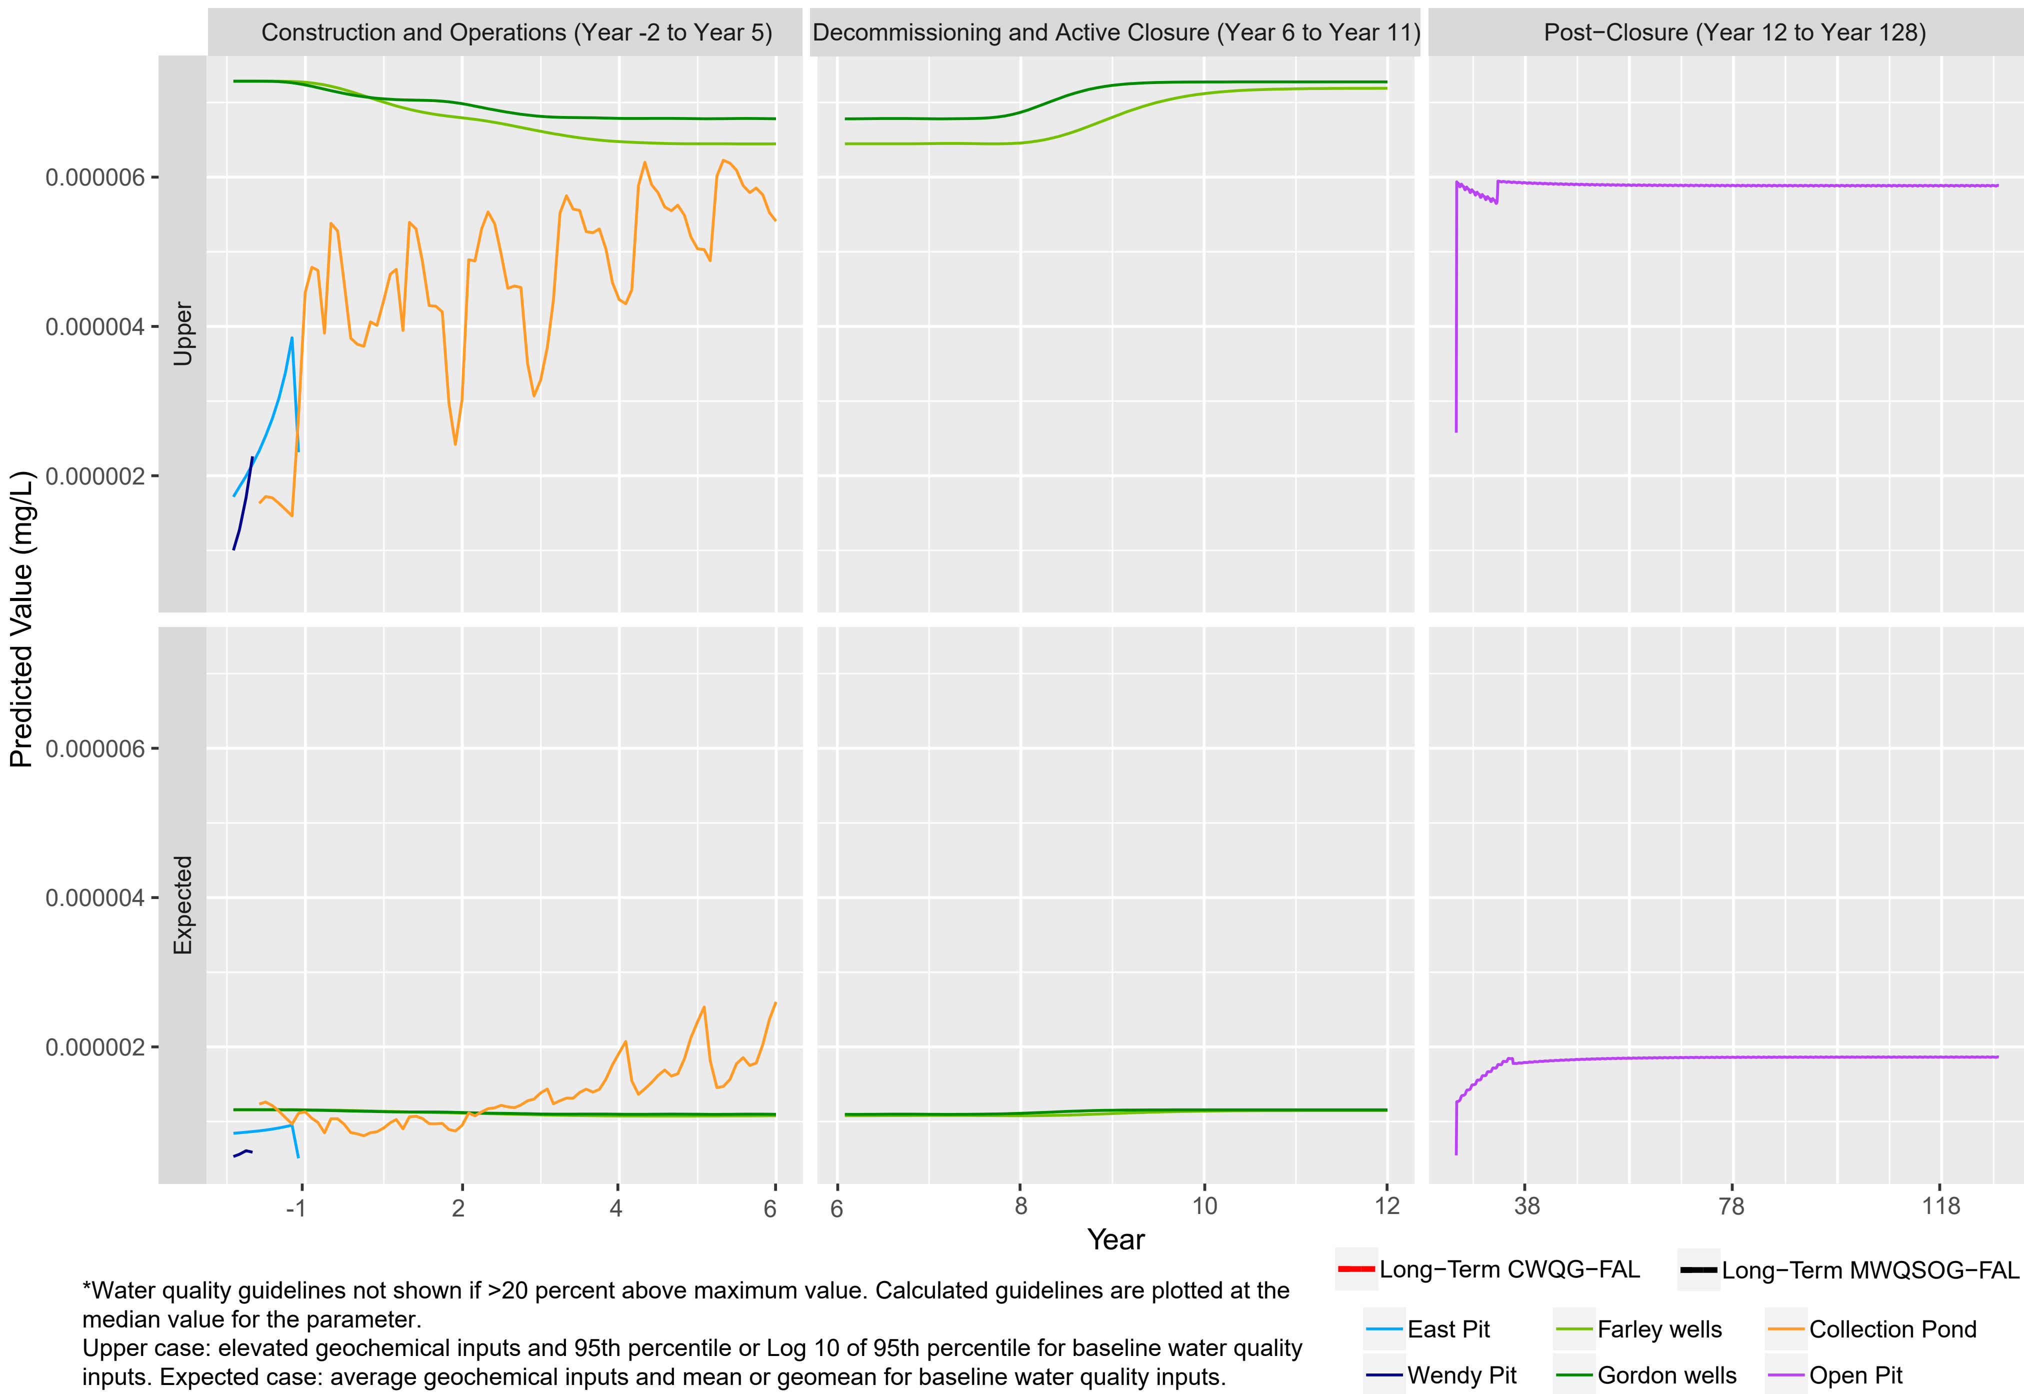
Manganese, Dissolved (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

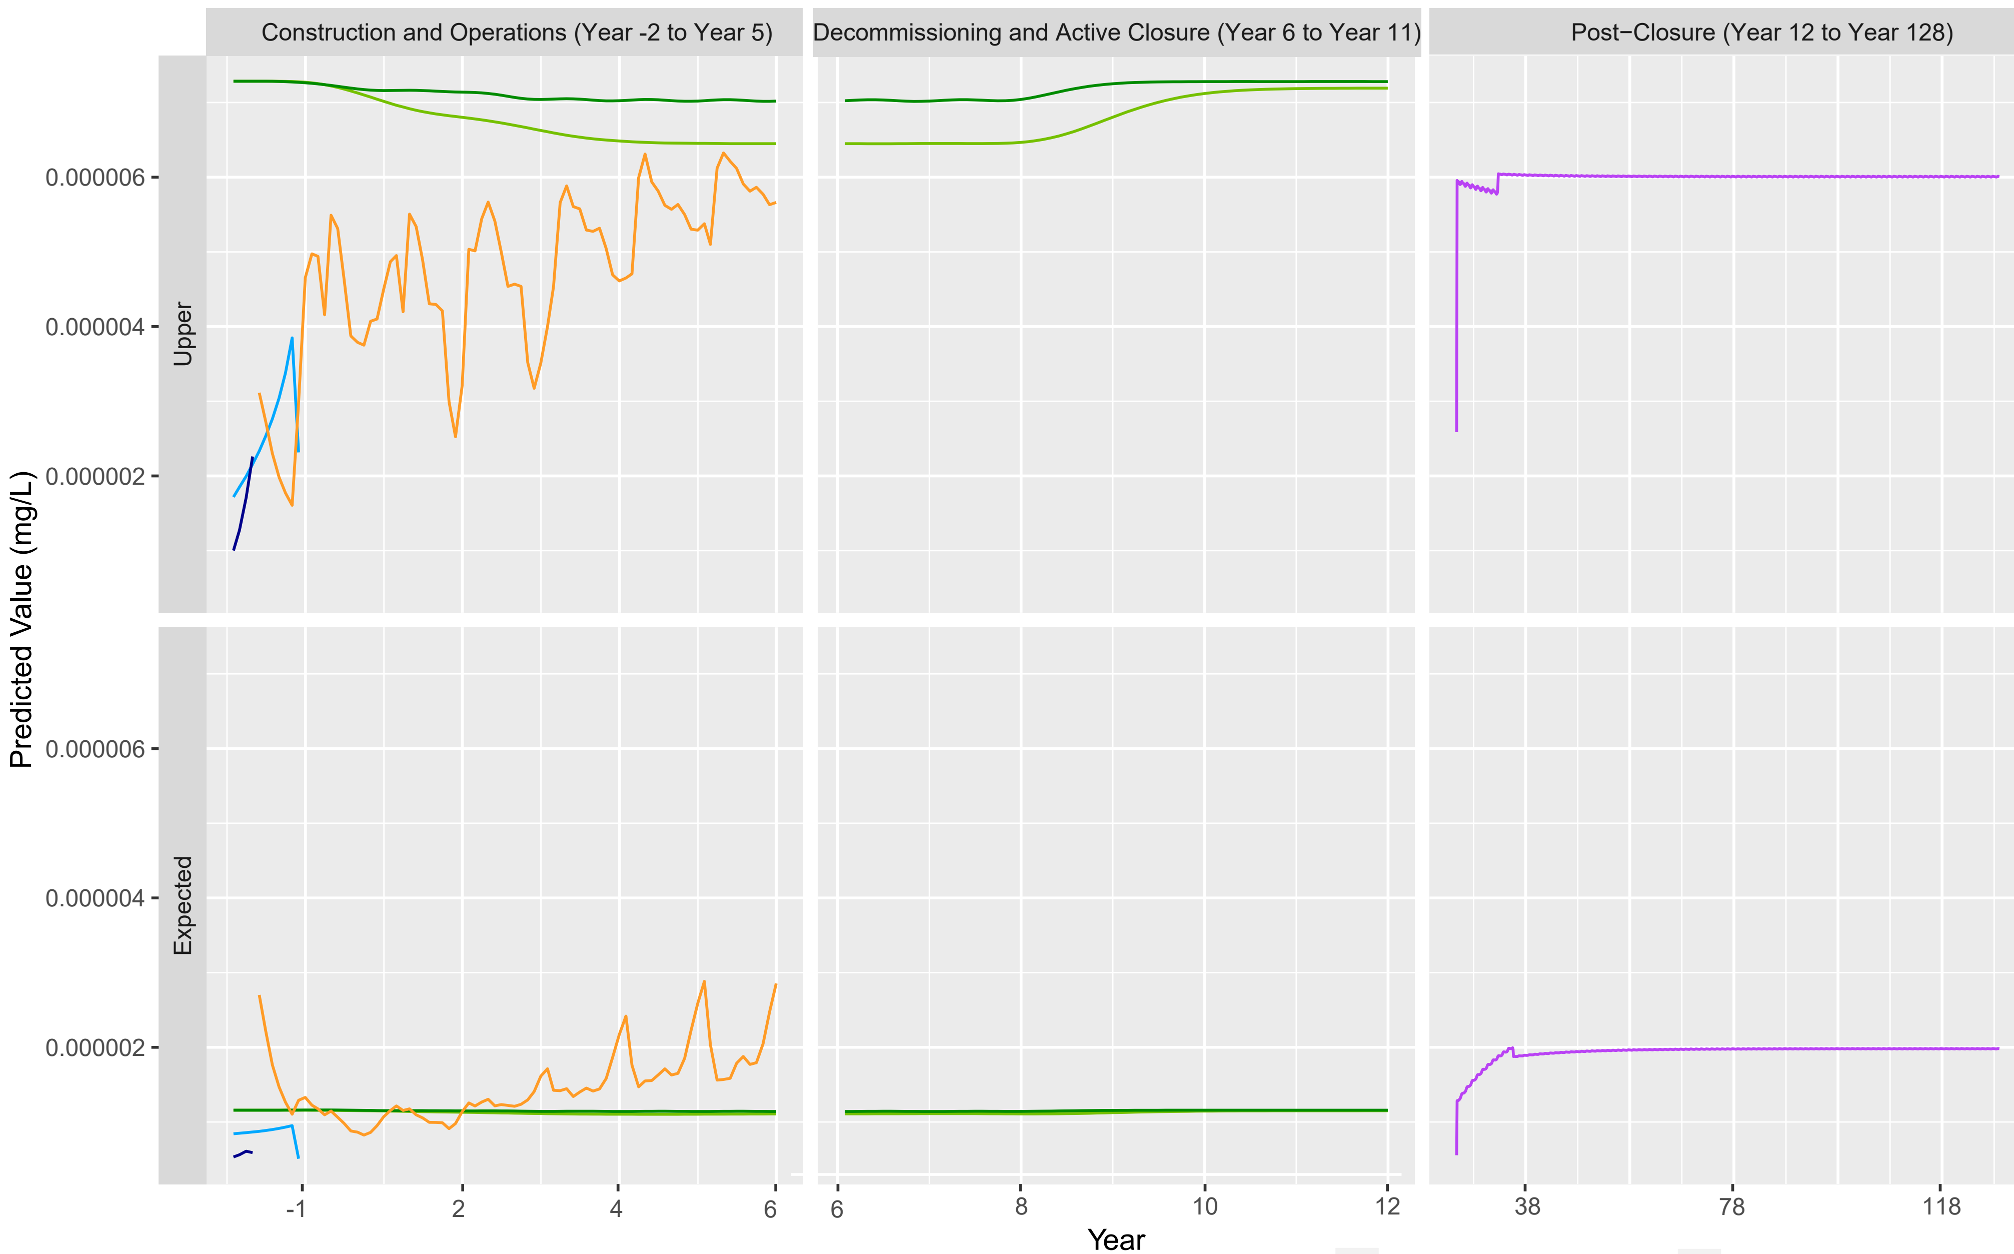
Mercury, Dissolved (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

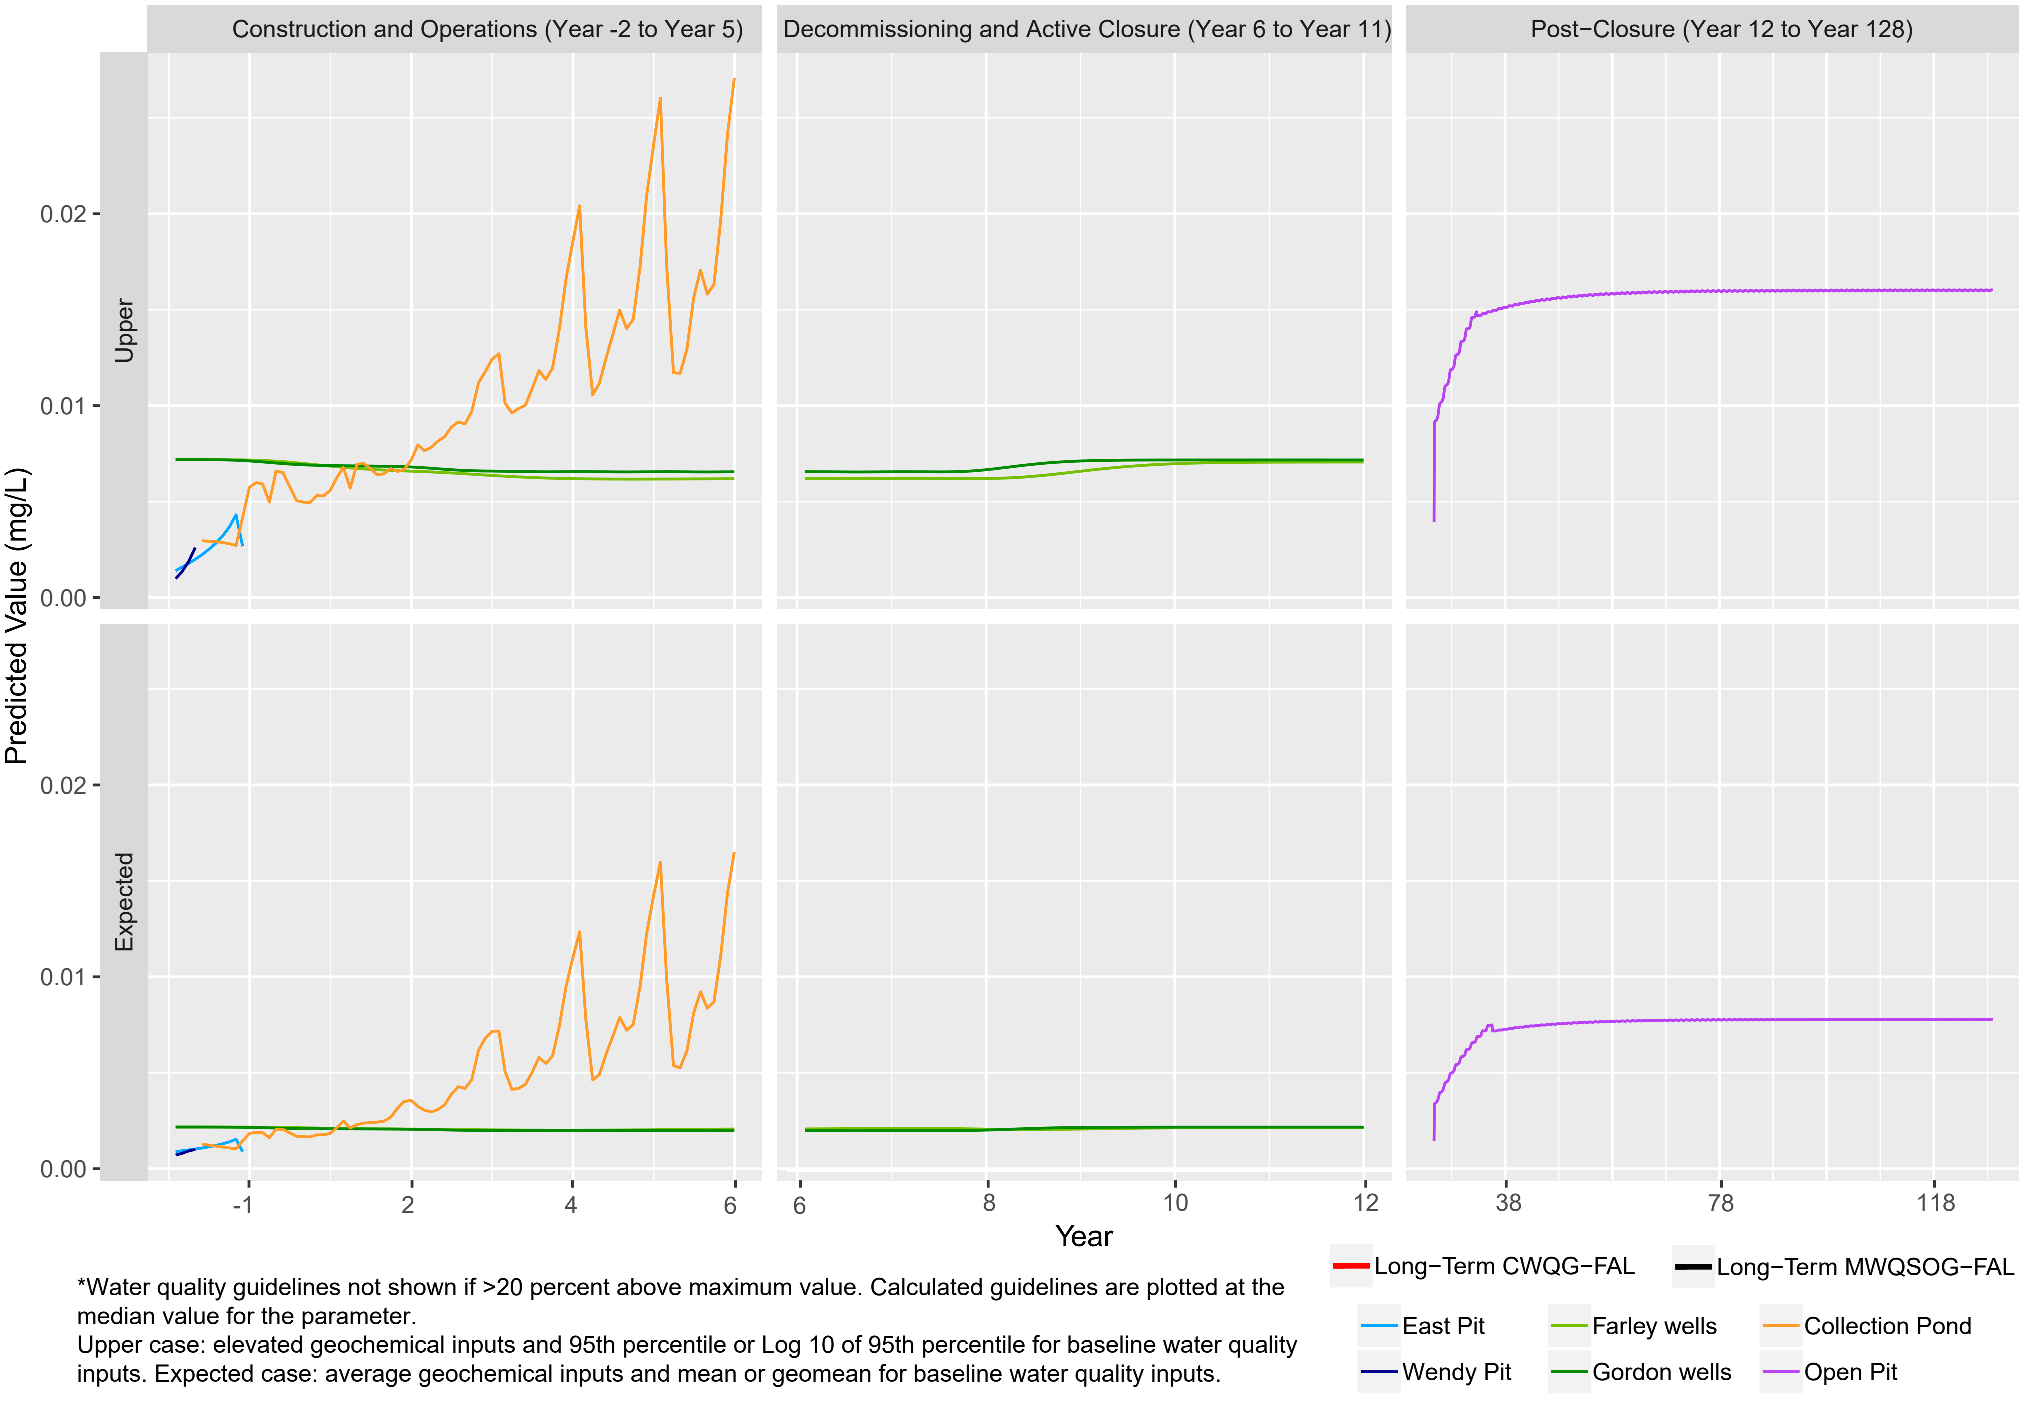
Mercury, Total (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

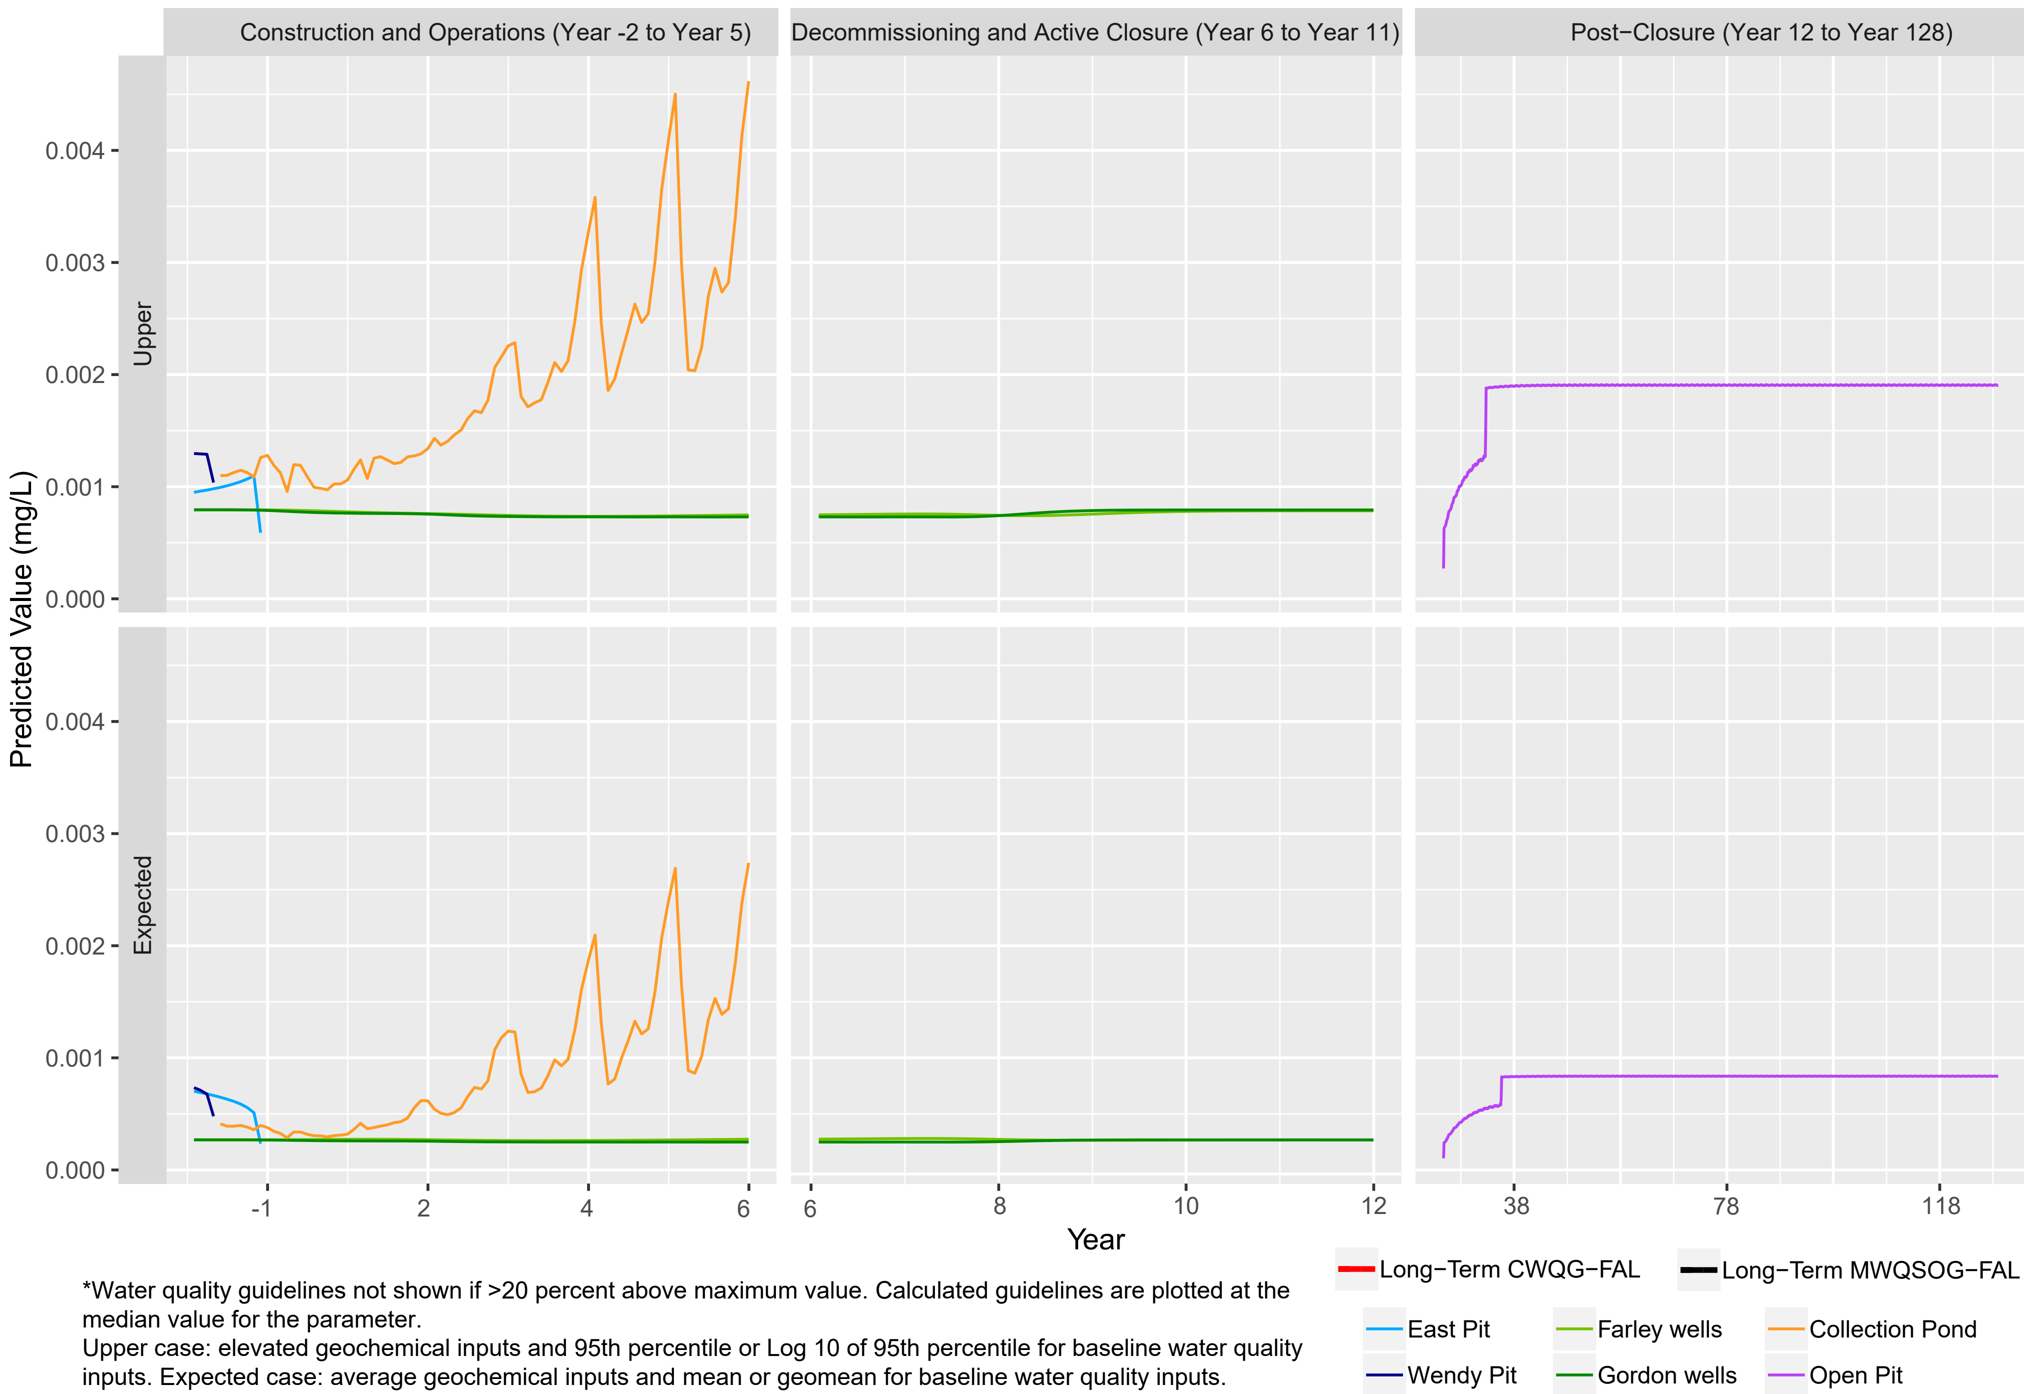
Molybdenum, Total (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

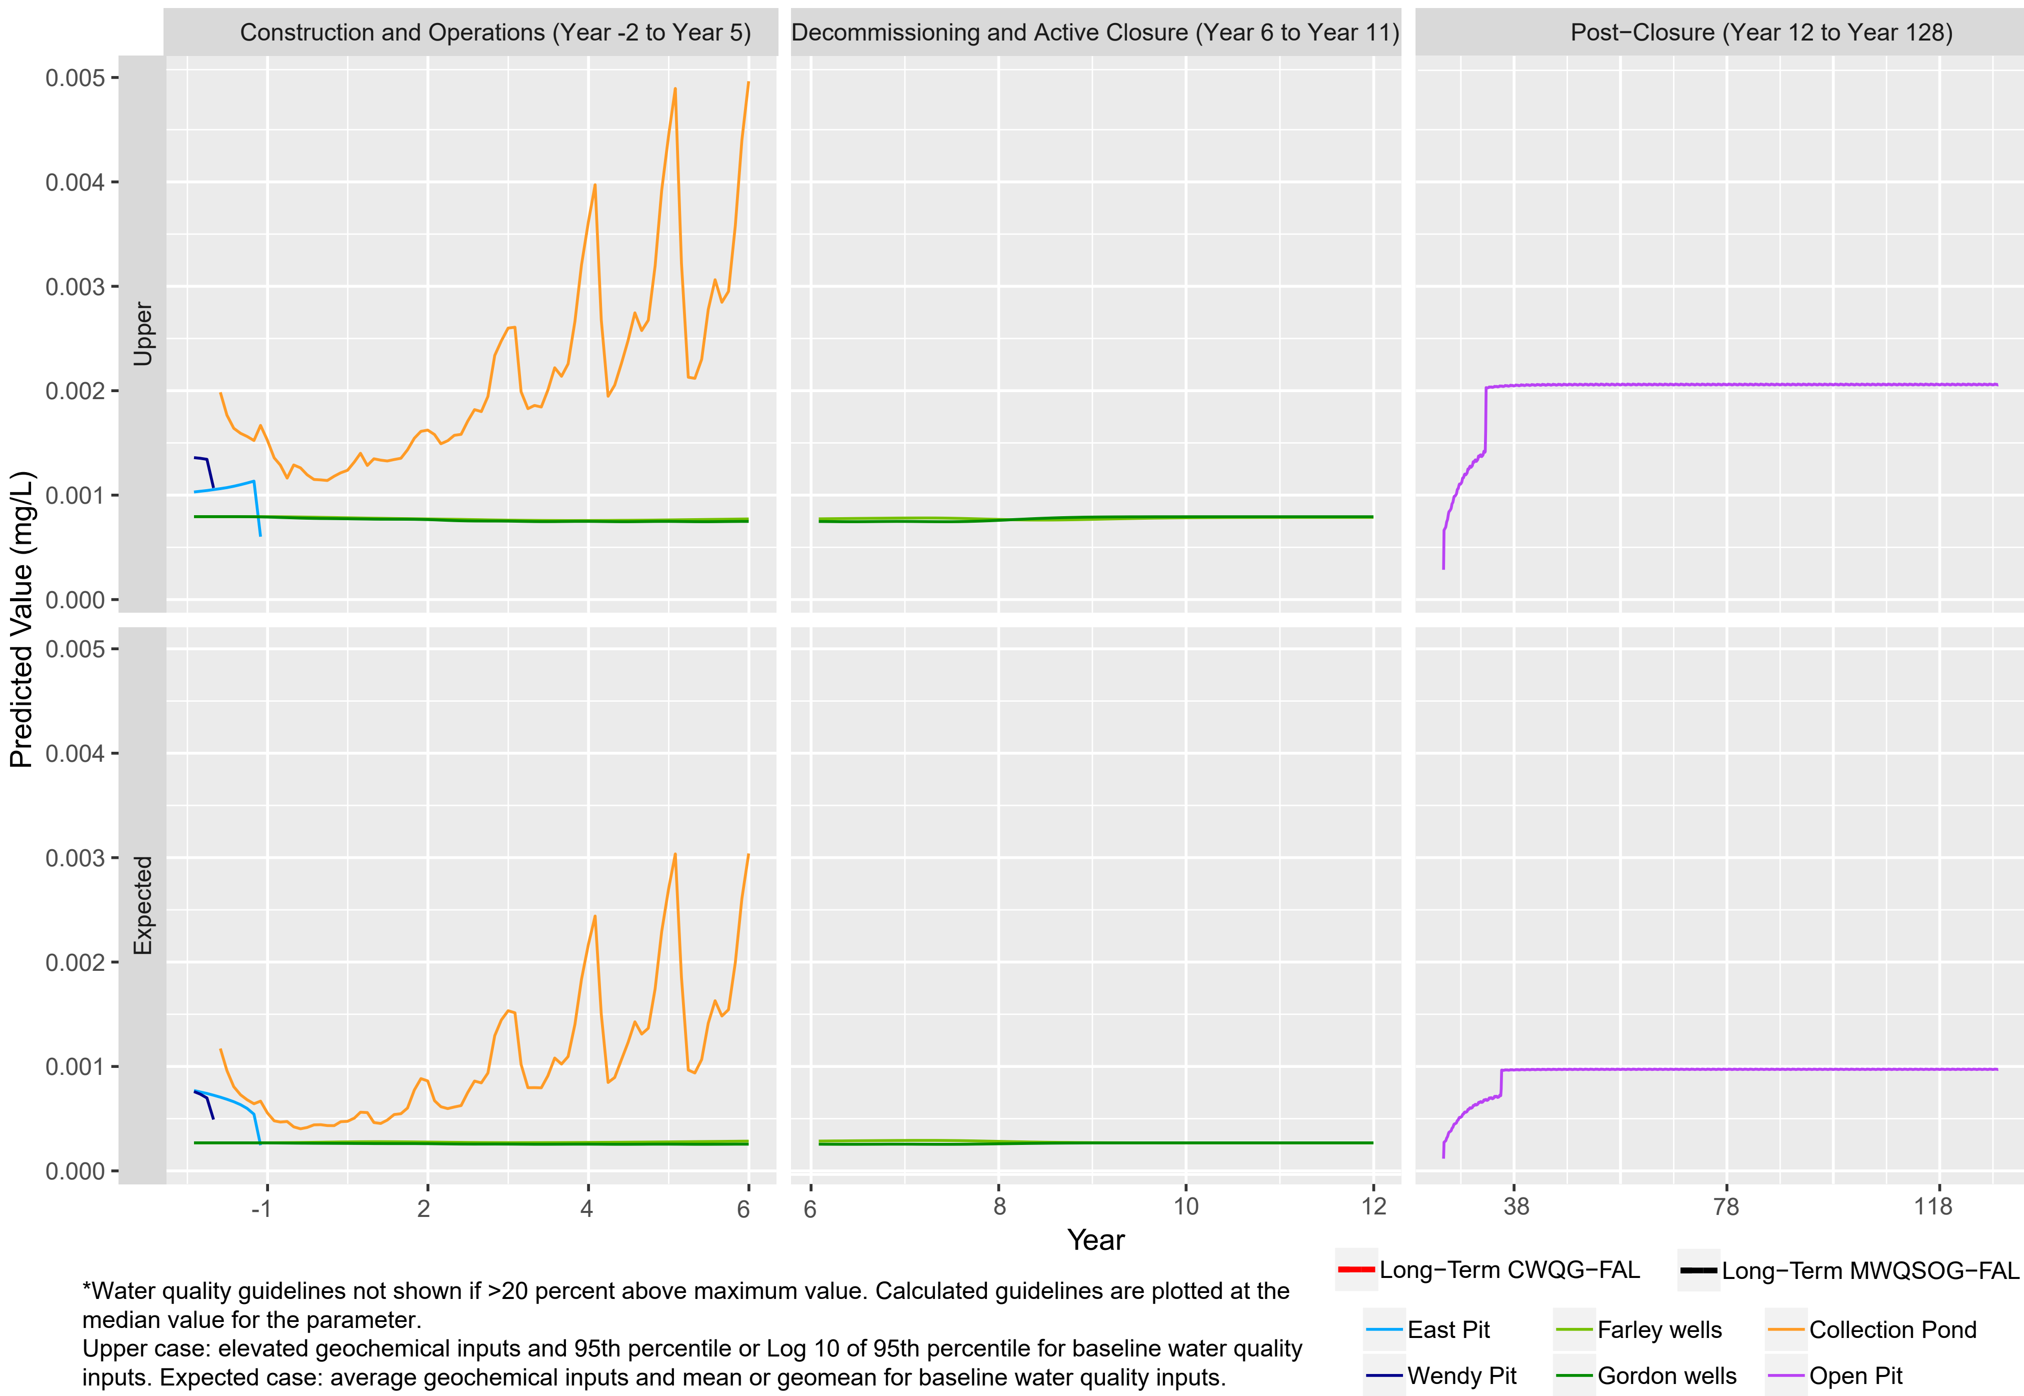
Nickel, Dissolved (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

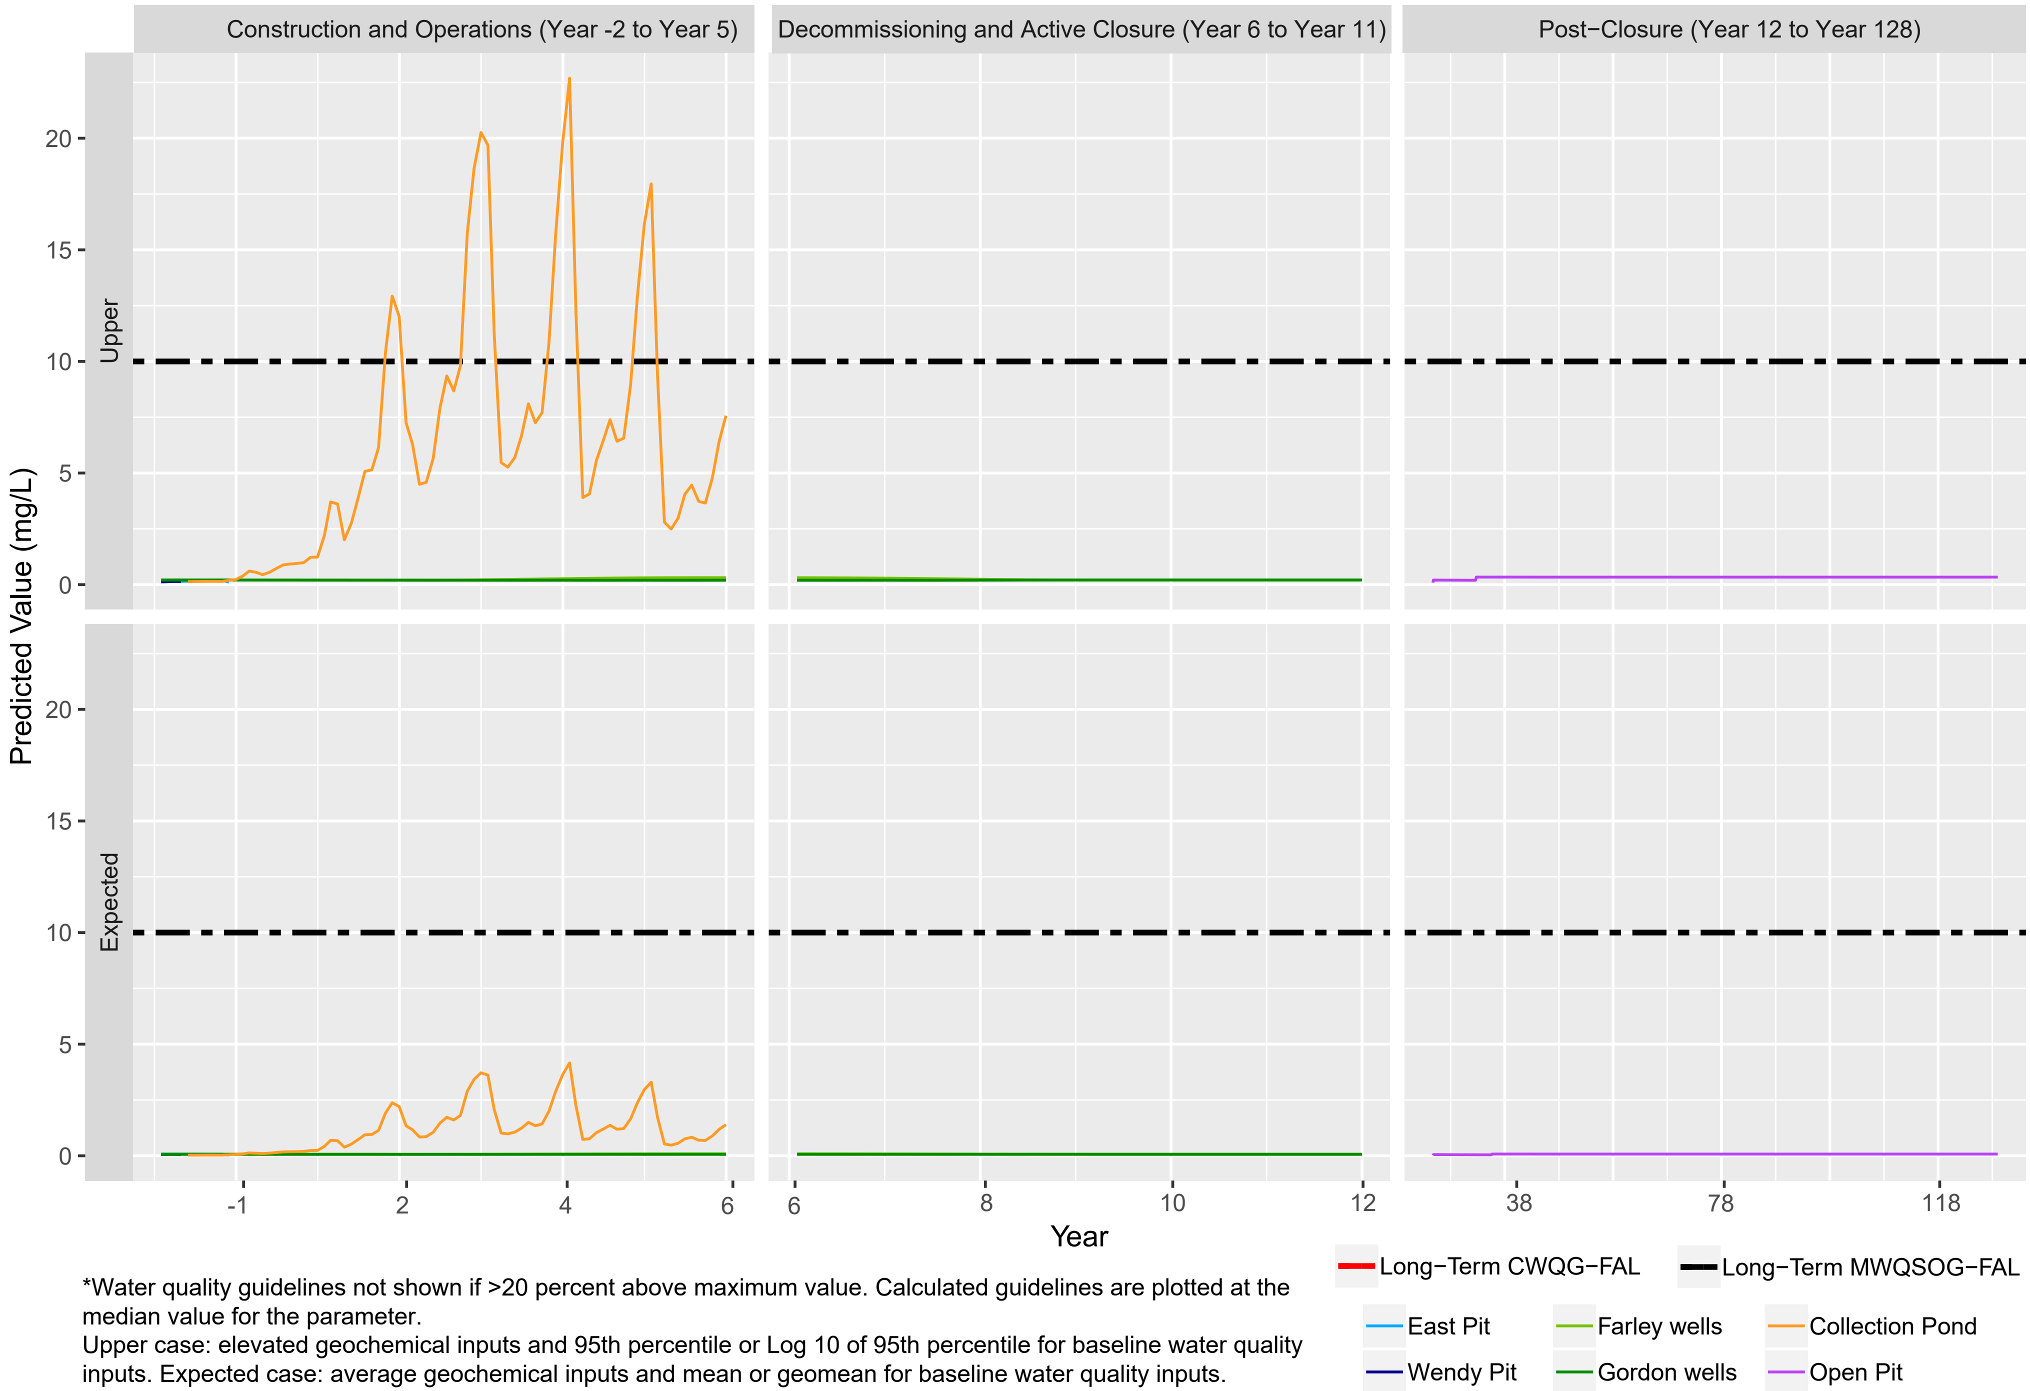
Nickel, Total (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

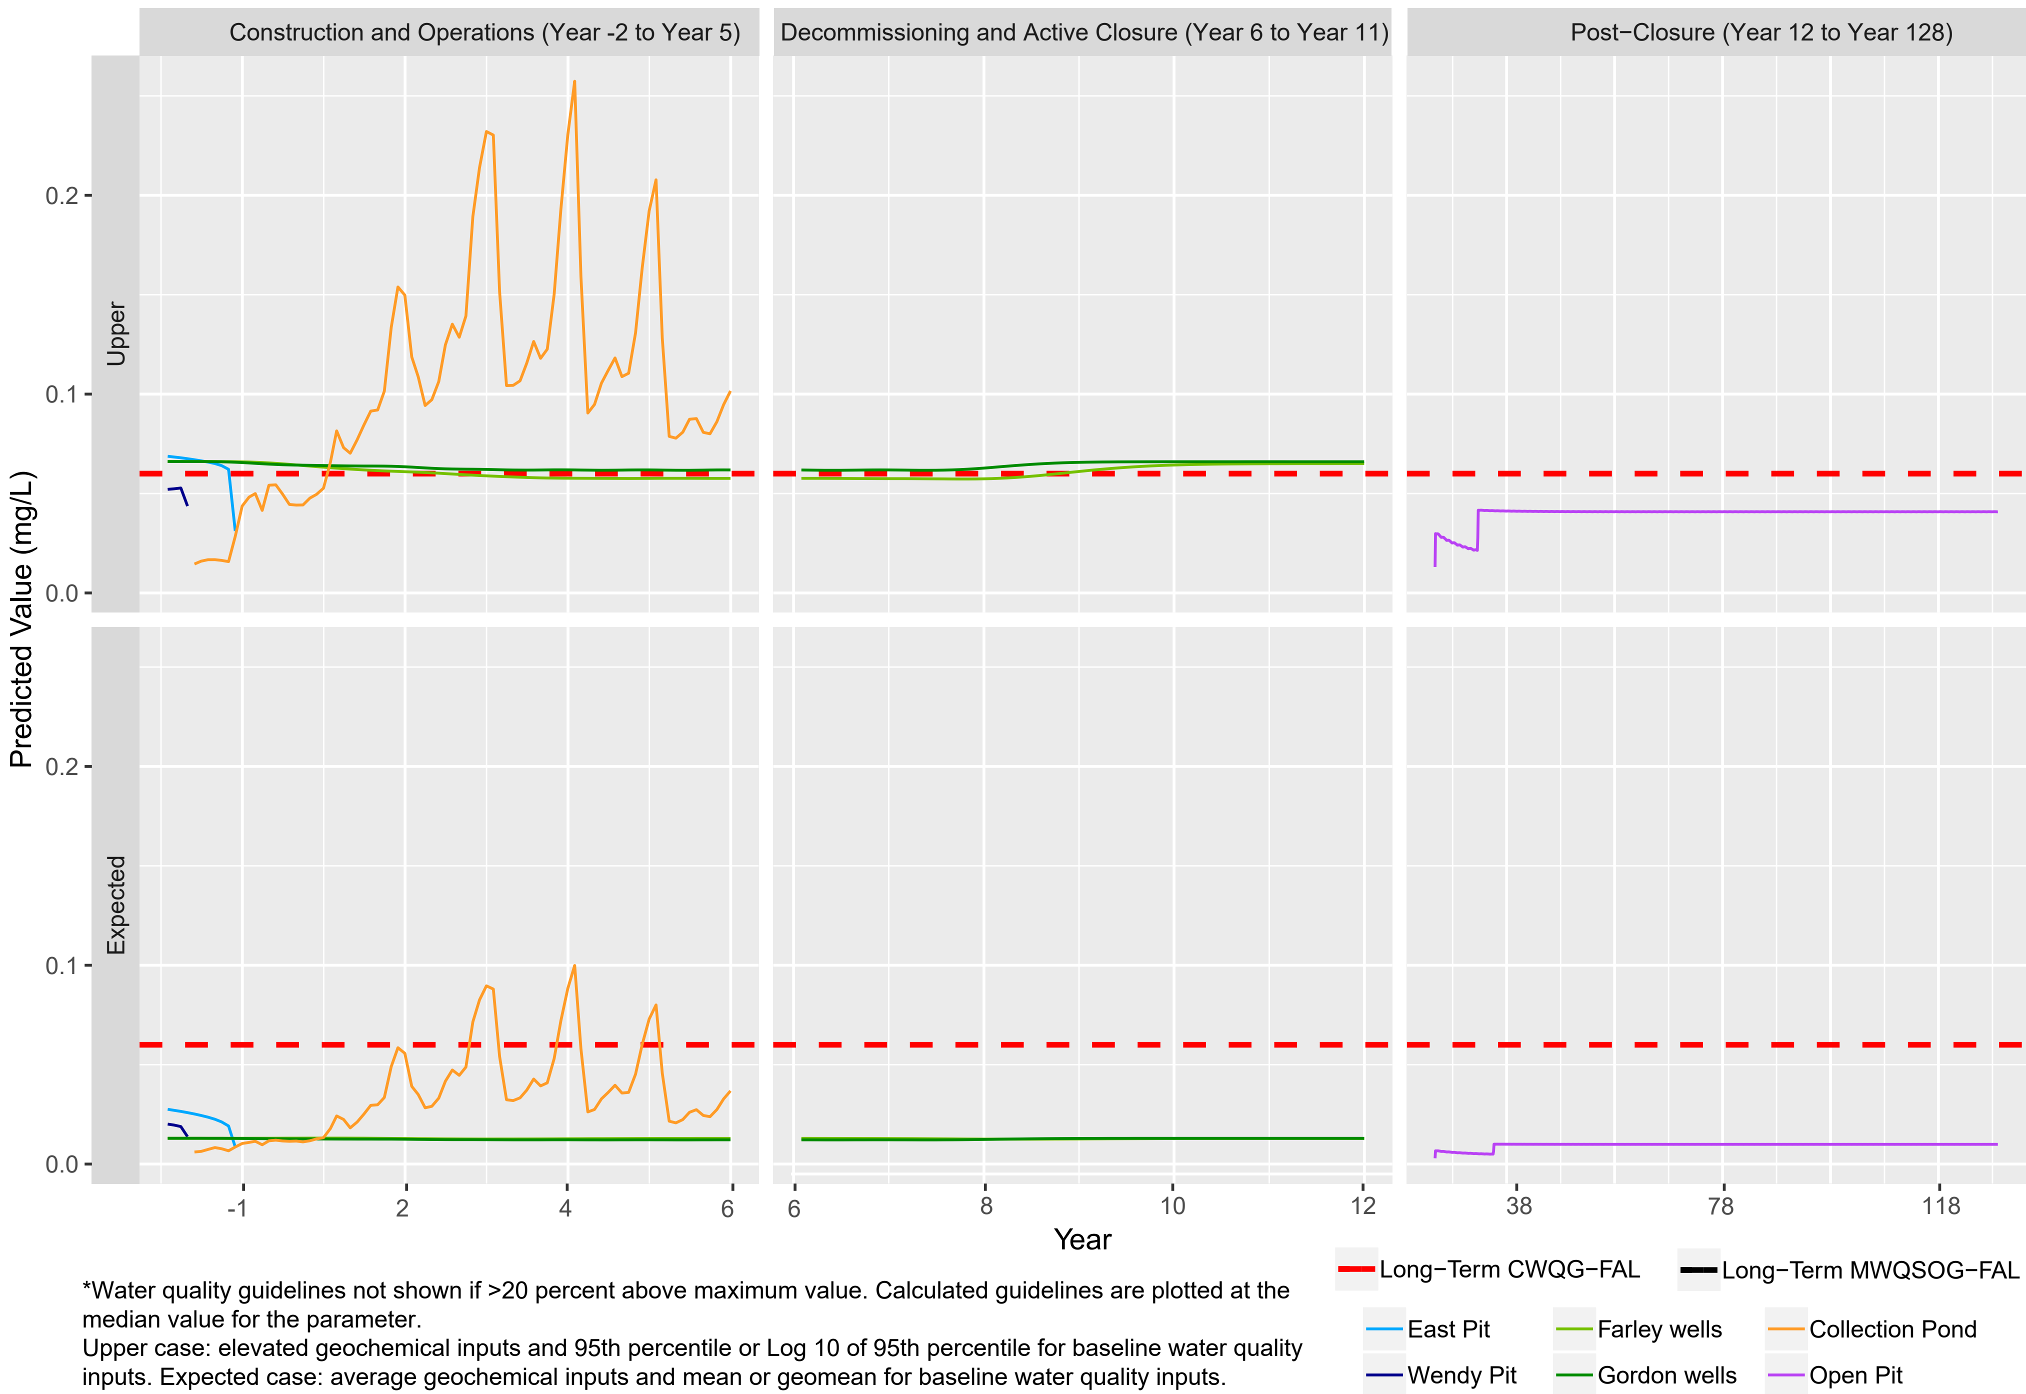
Nitrate + Nitrite (as N), (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

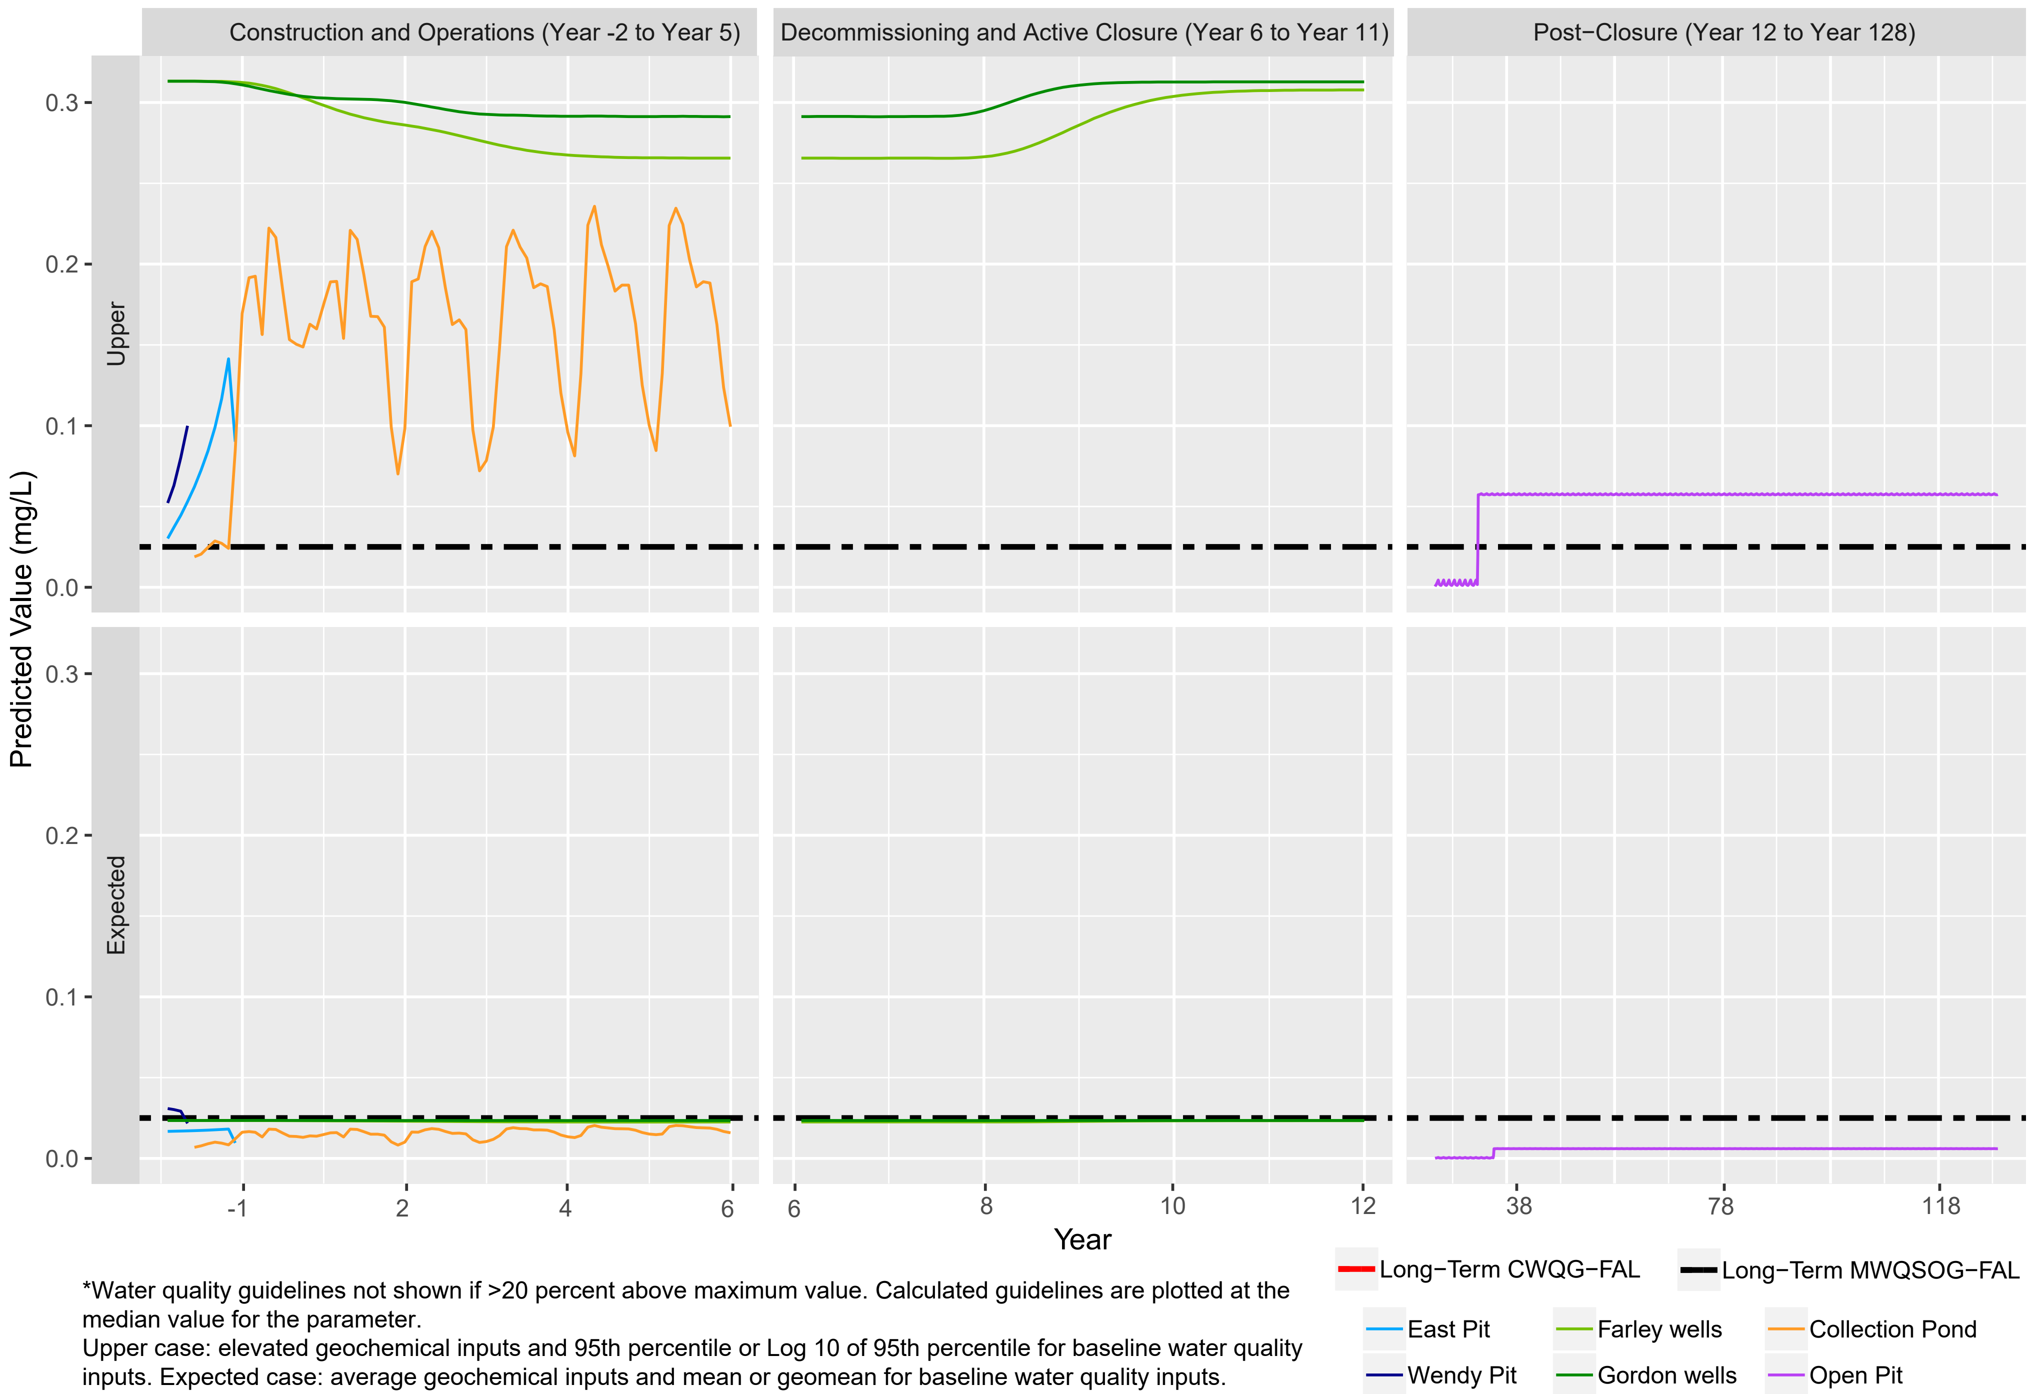
Nitrite (as N) (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

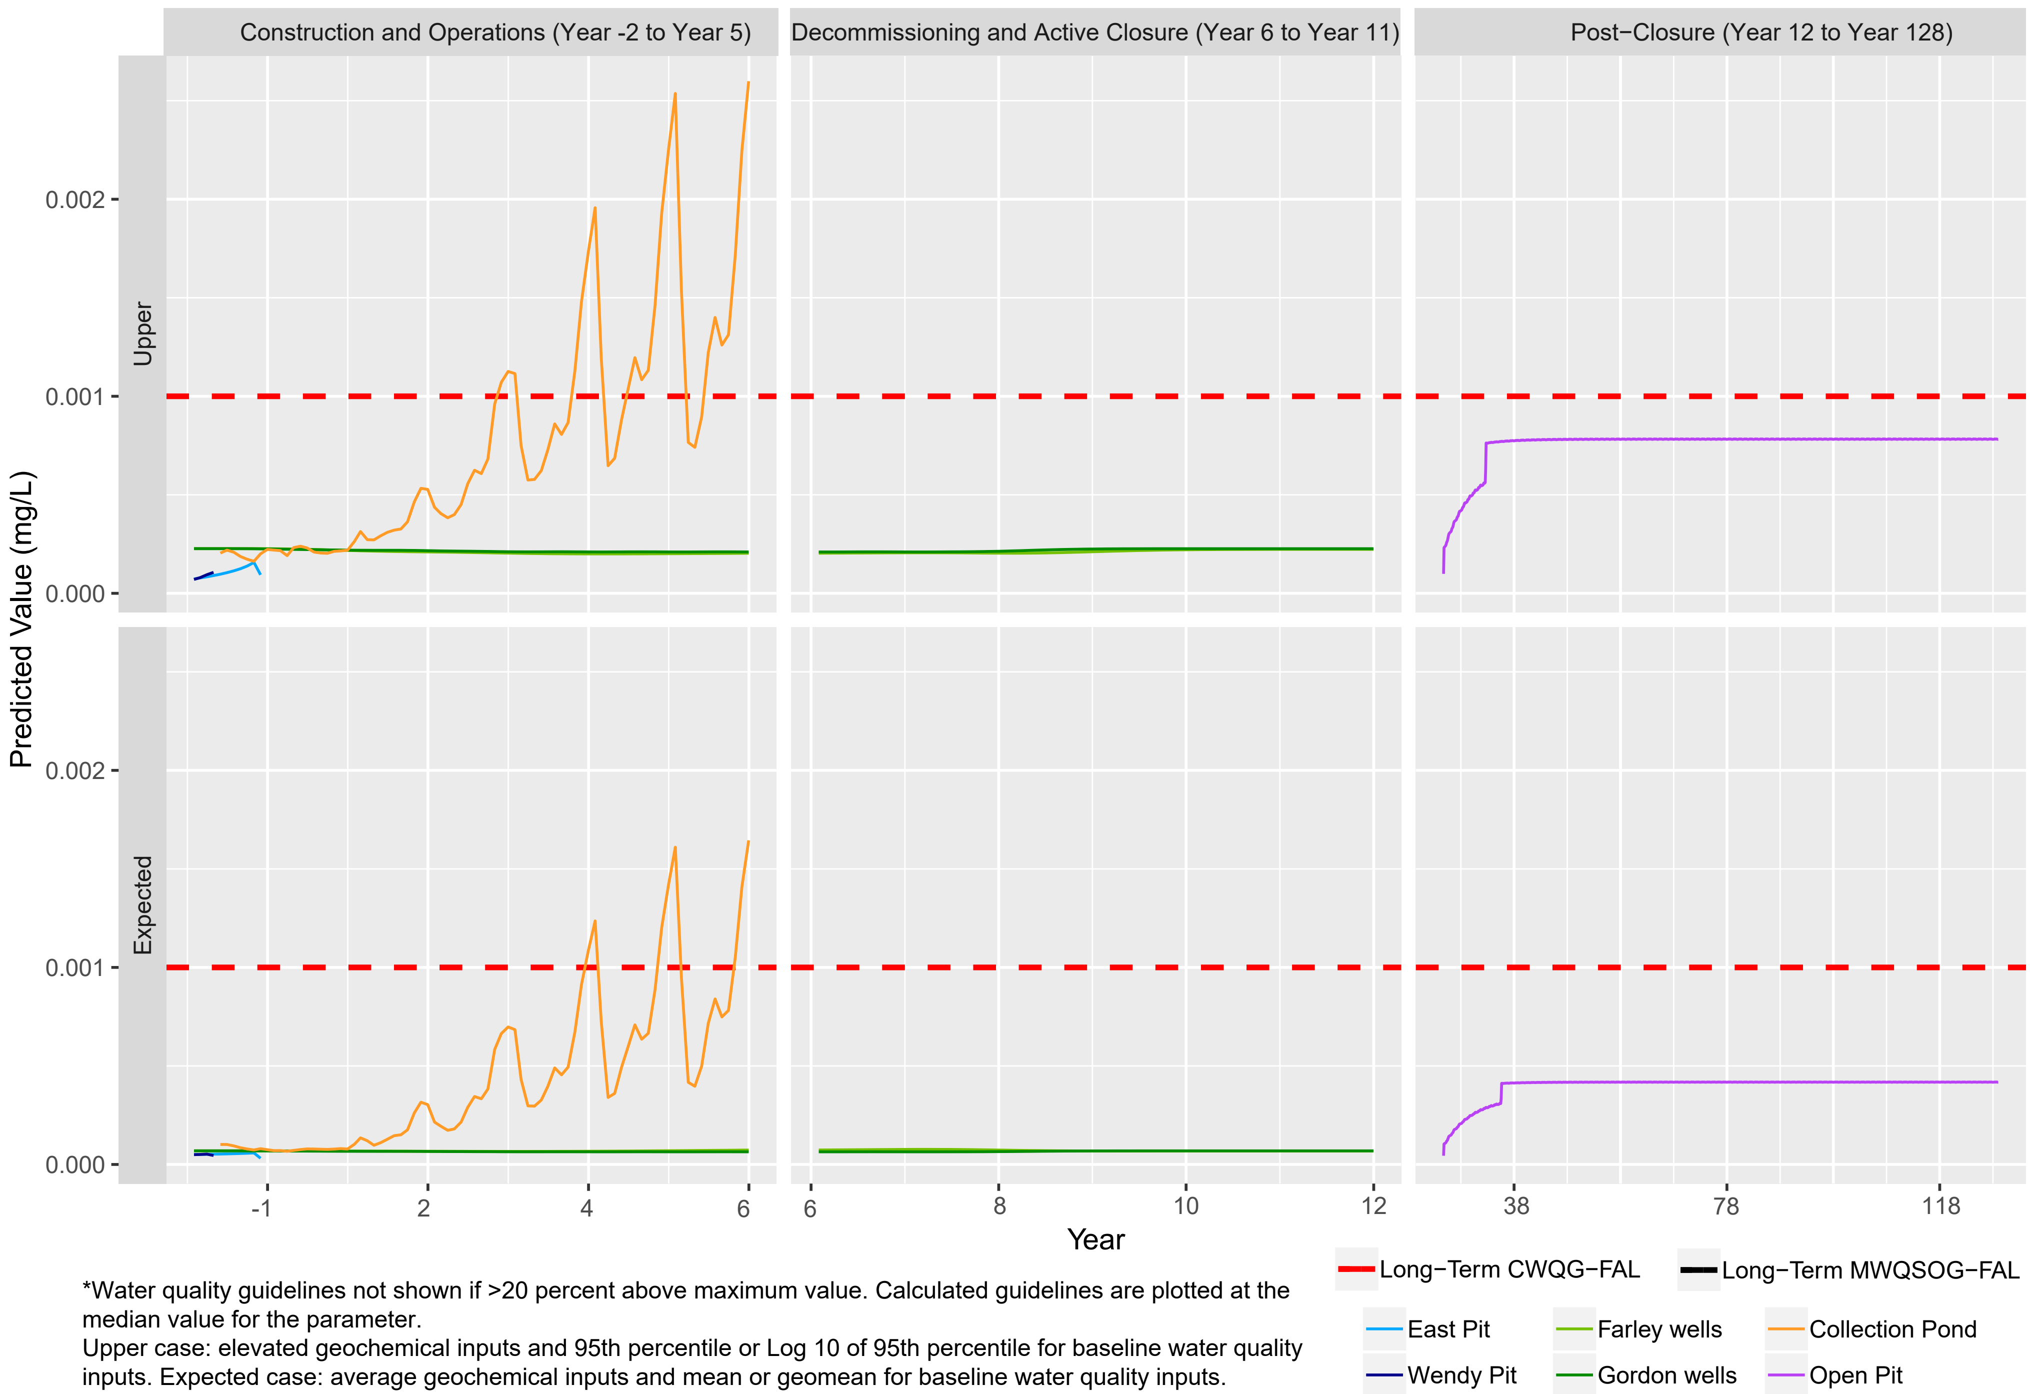
Phosphorus, Total, (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

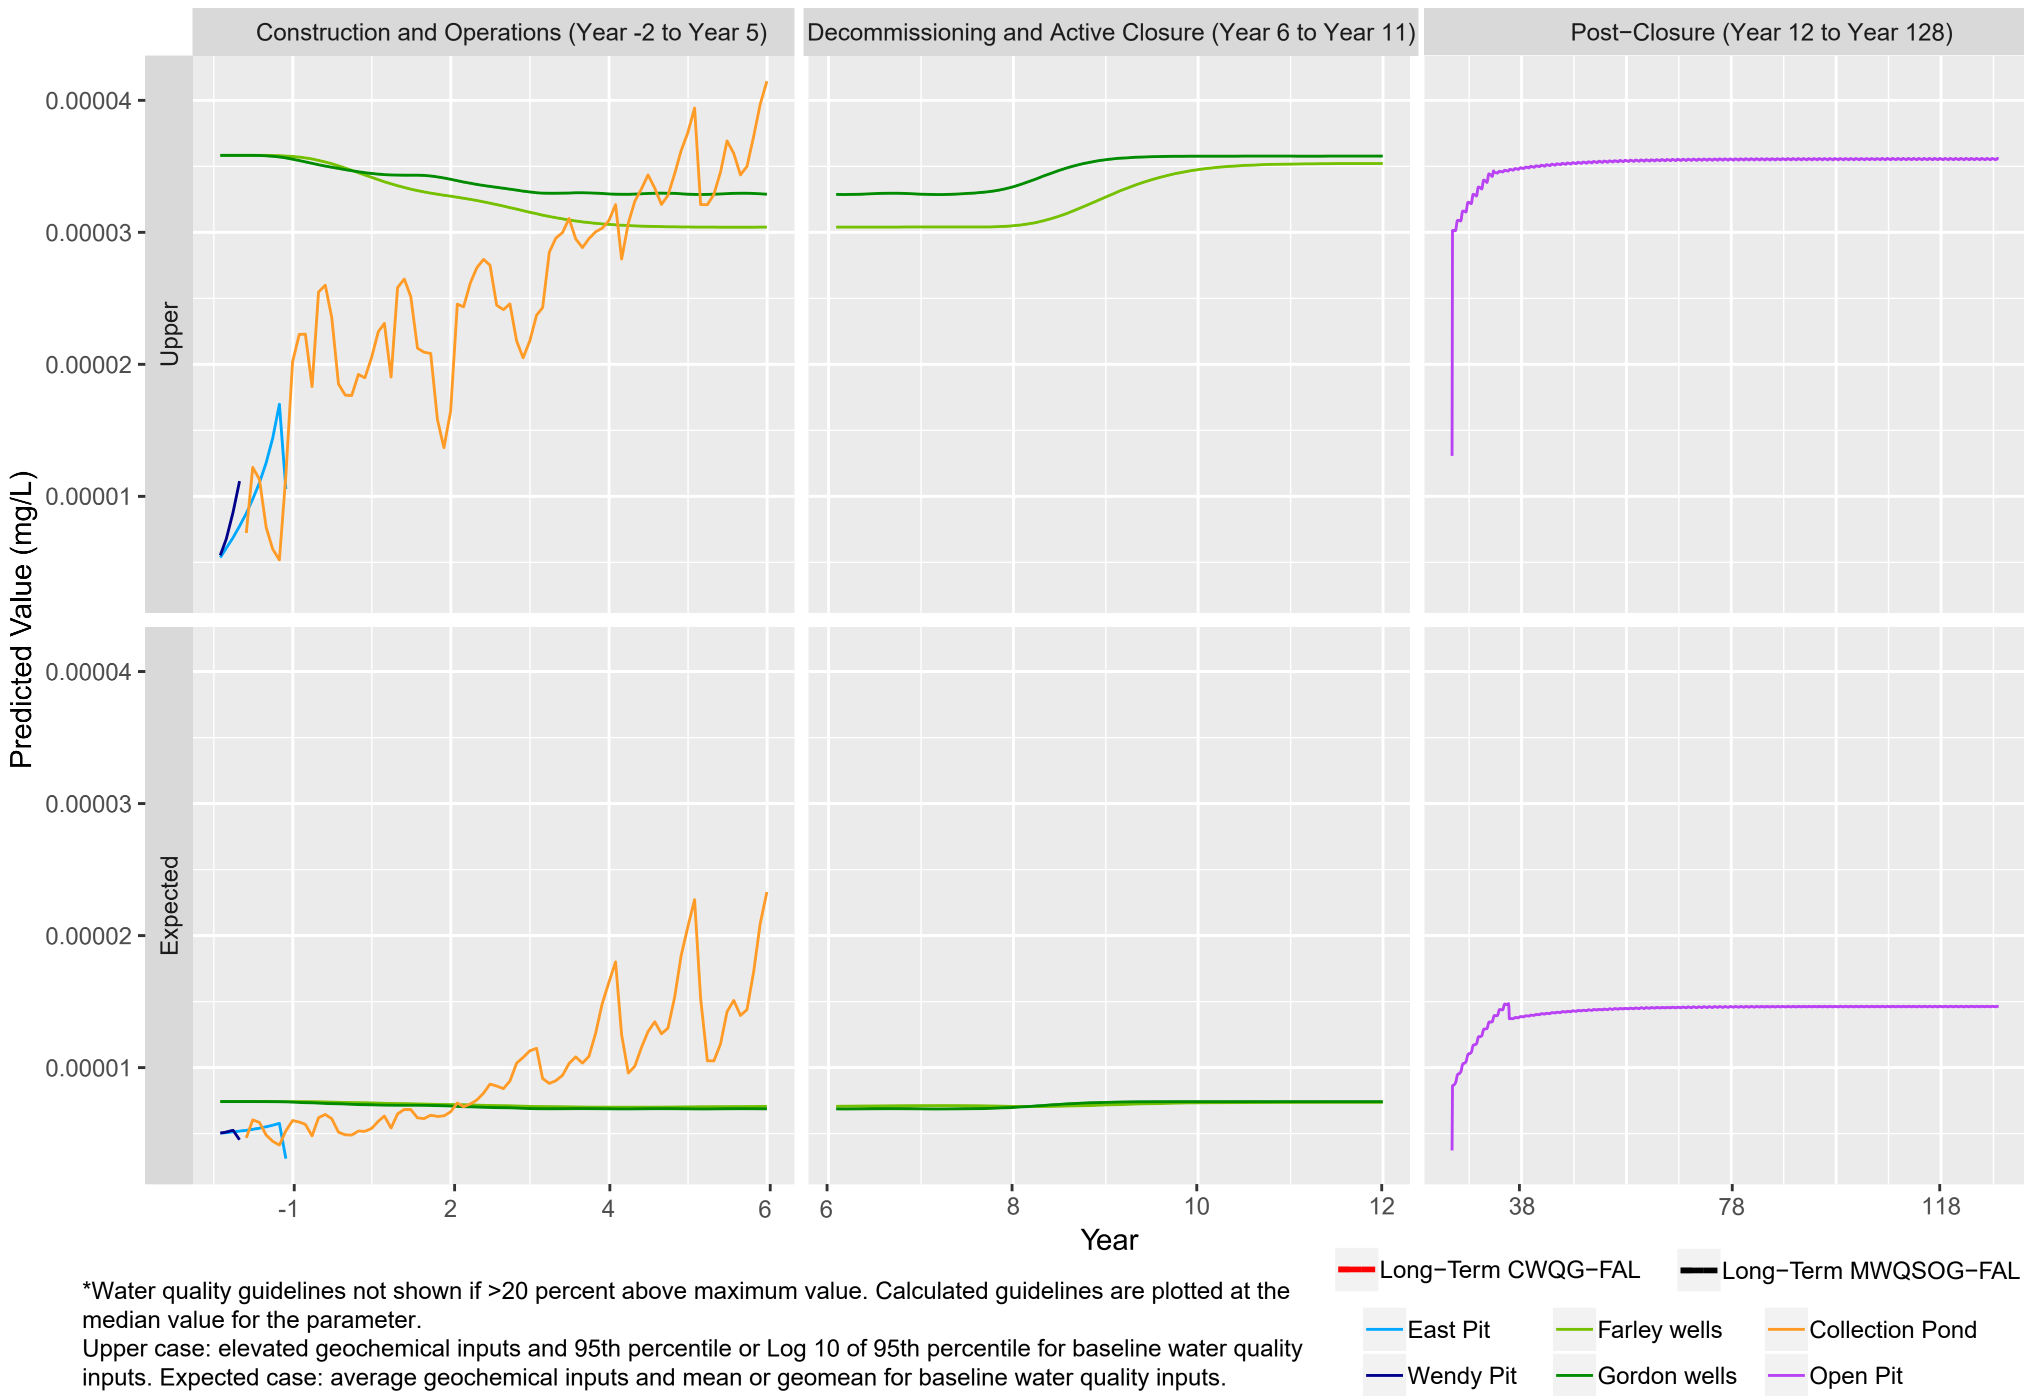
Selenium, Total (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

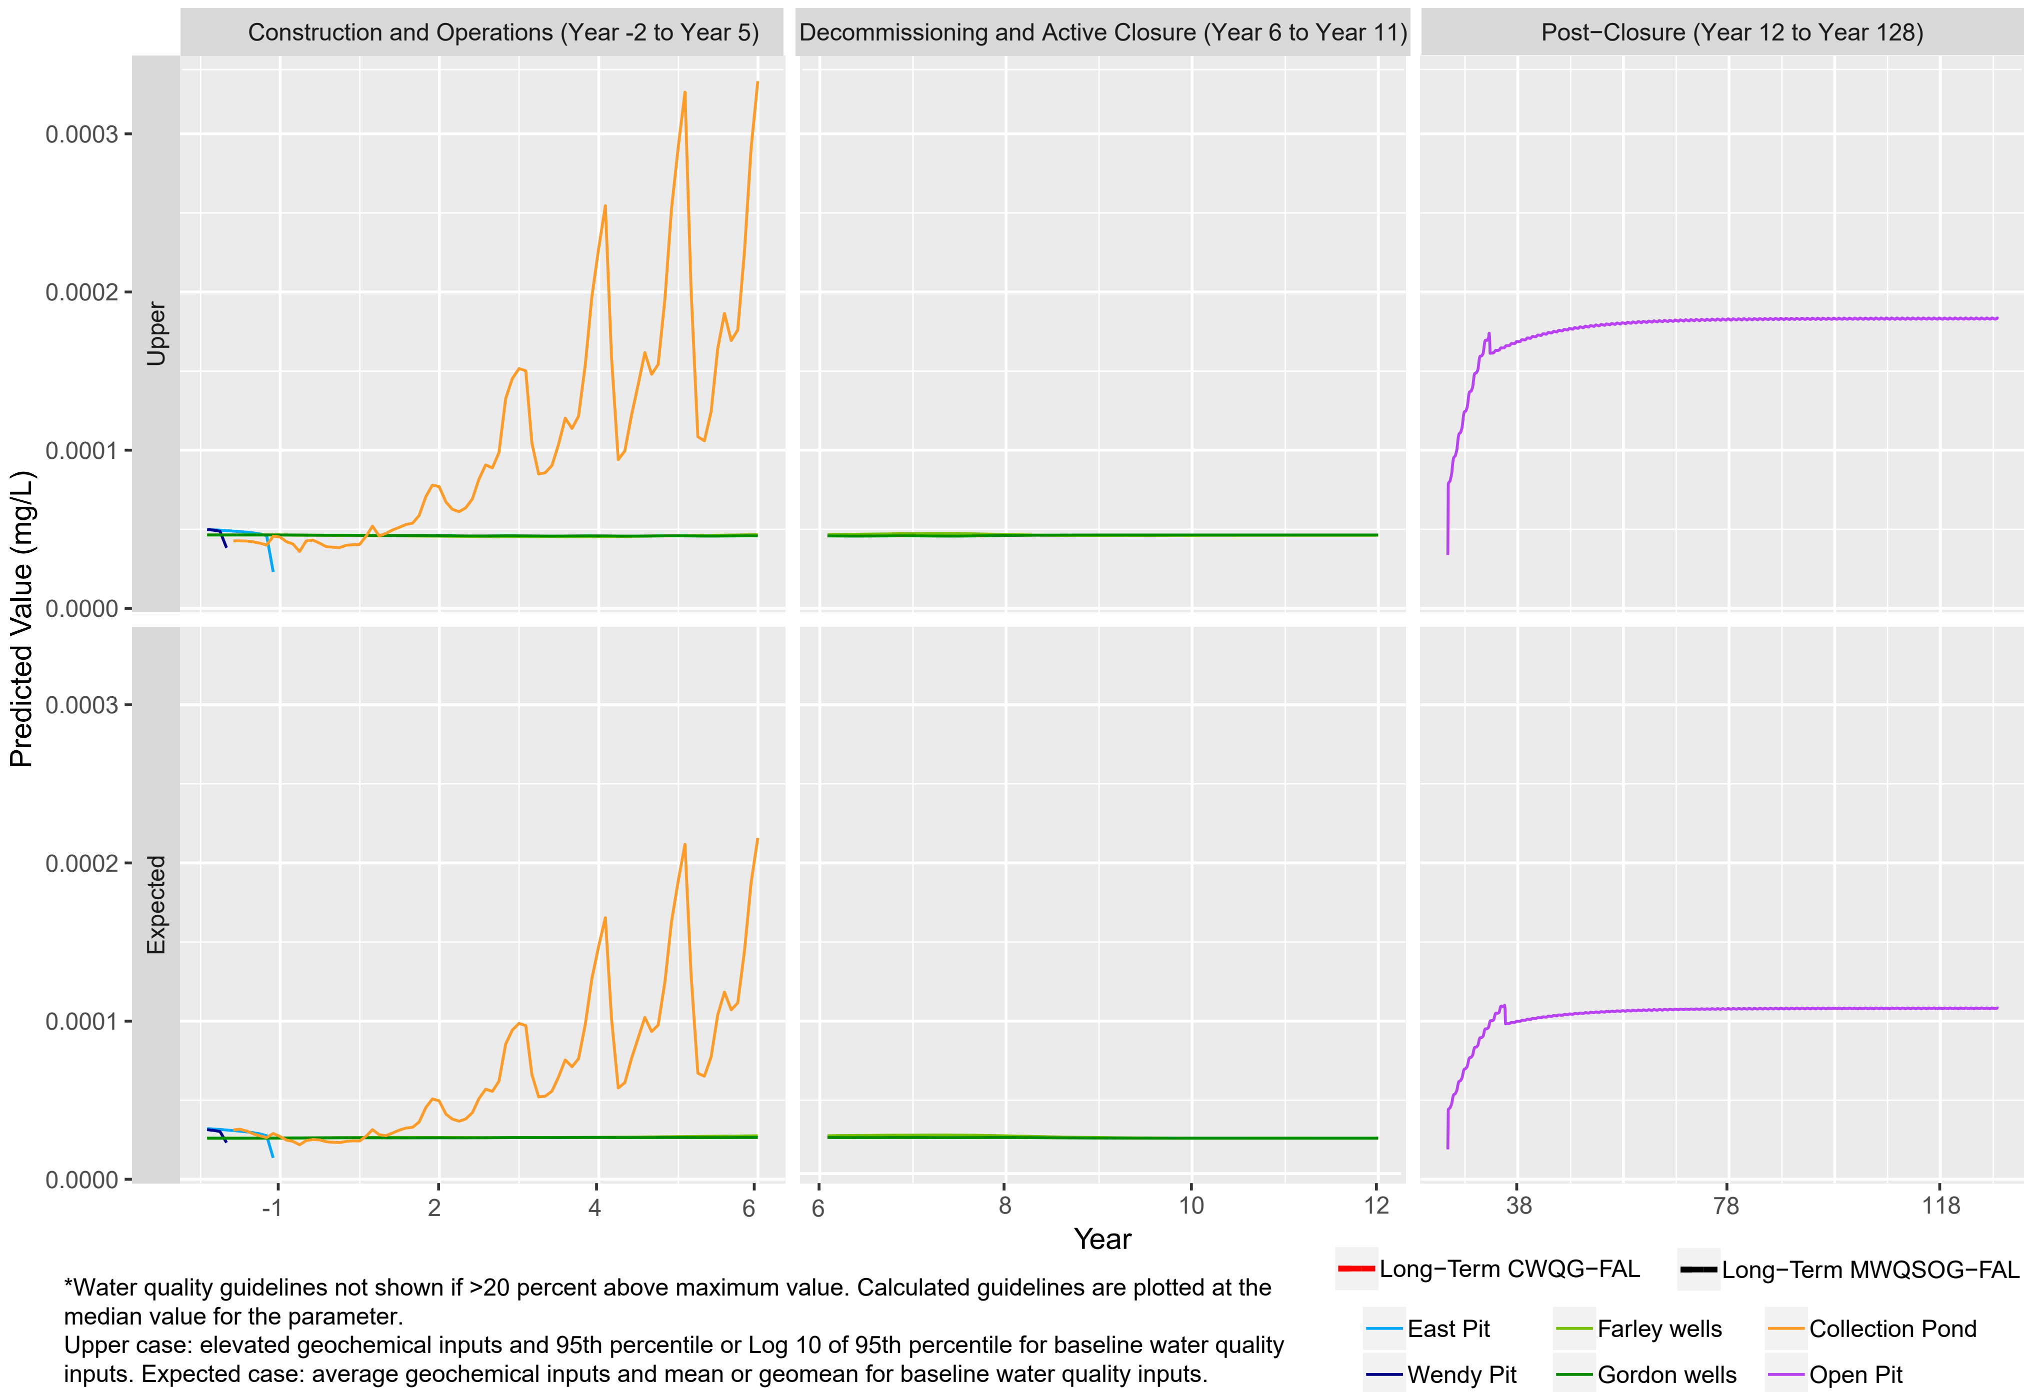
Silver, Total (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

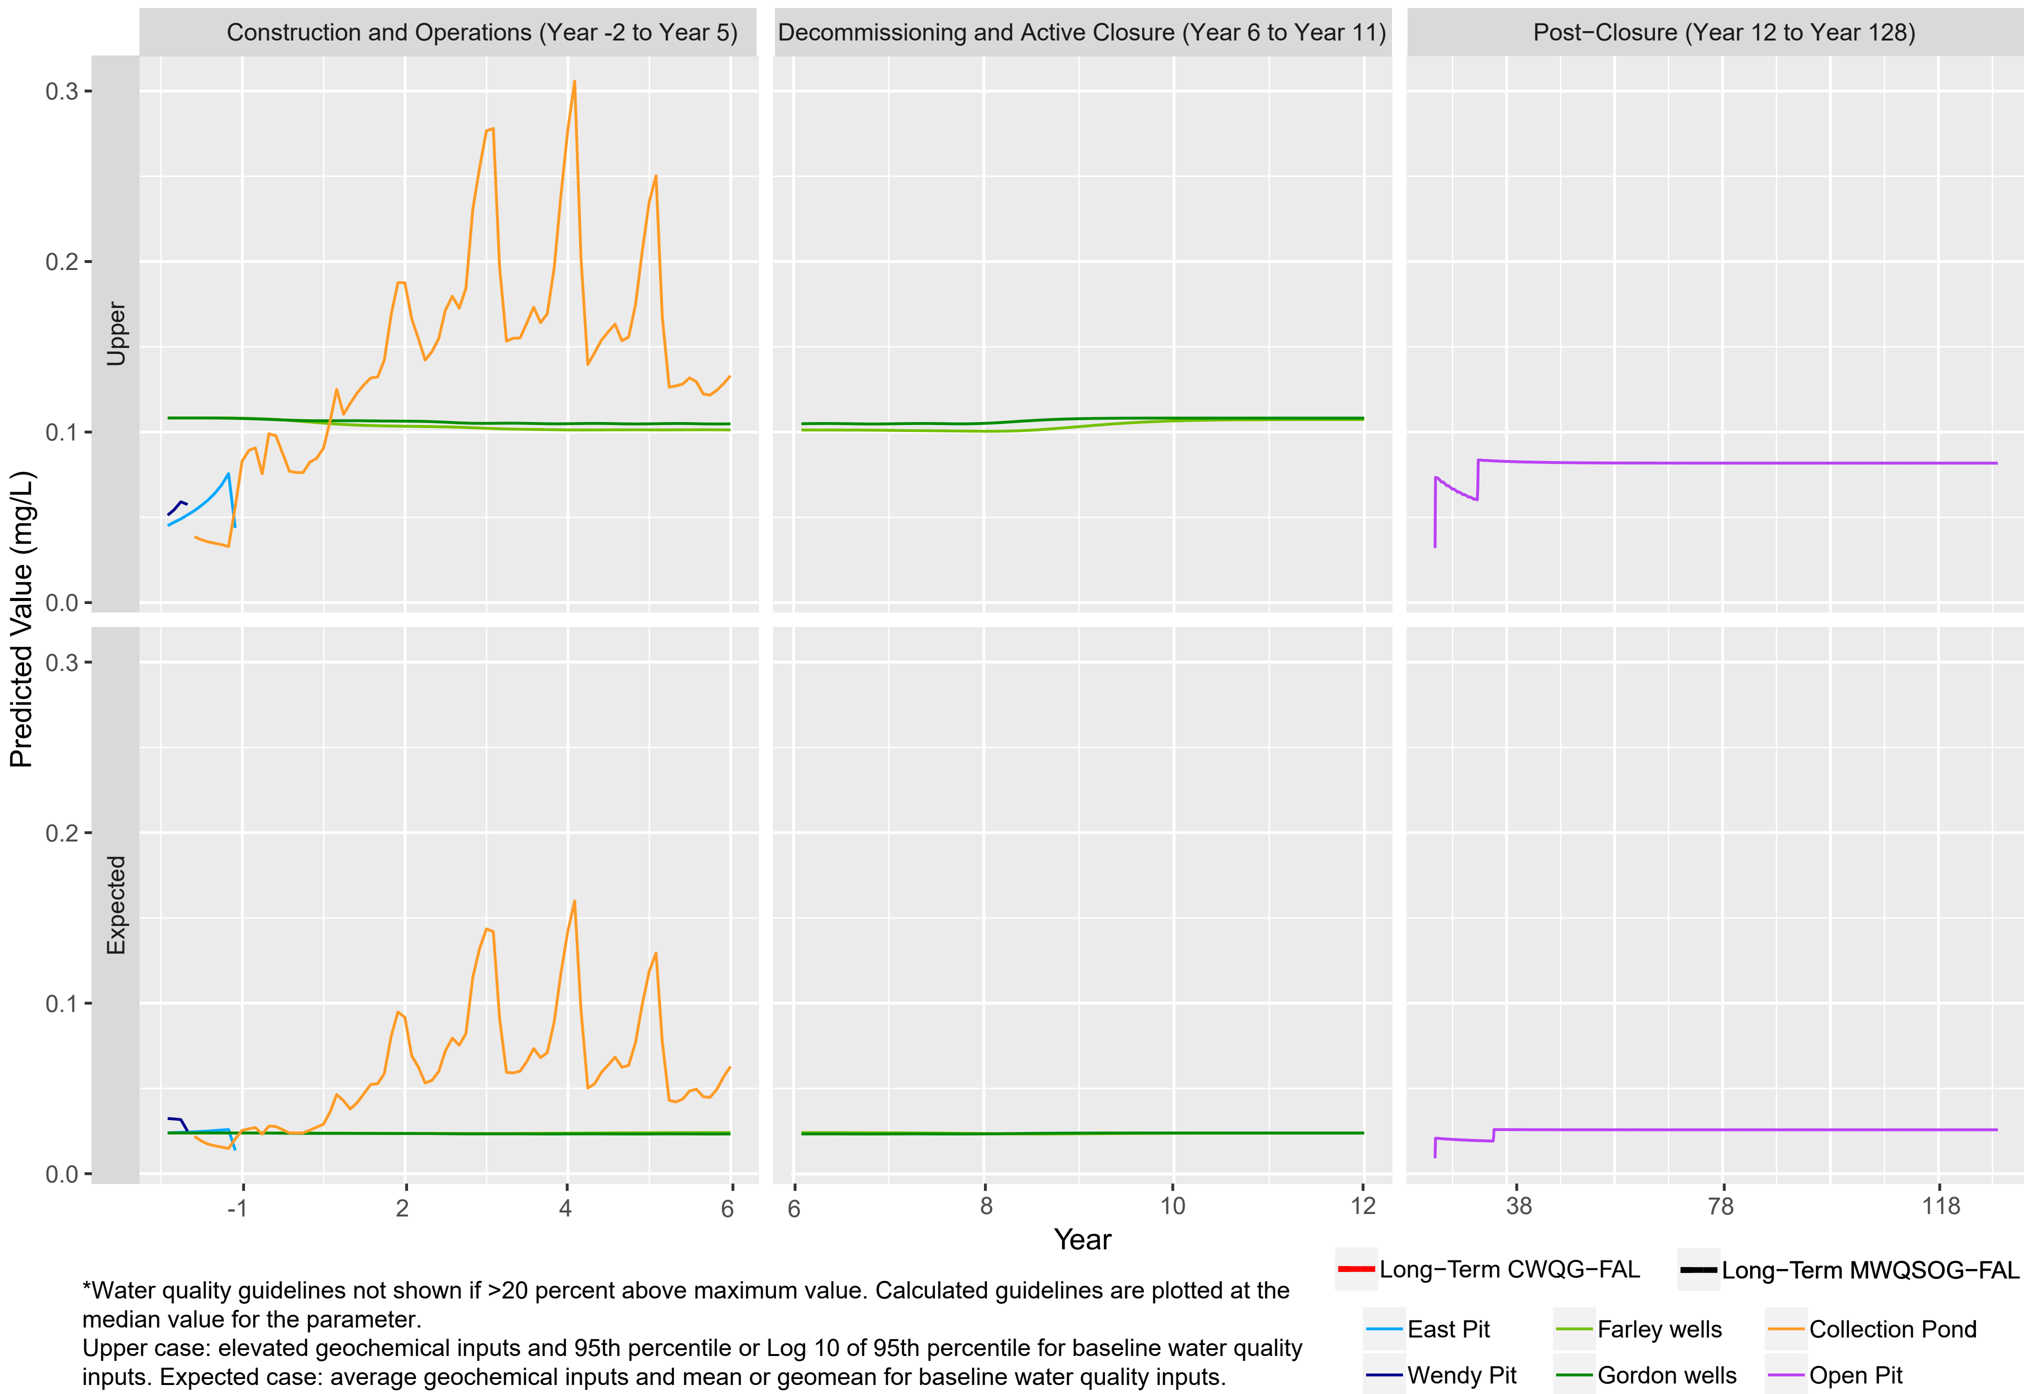
Thallium, Total (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

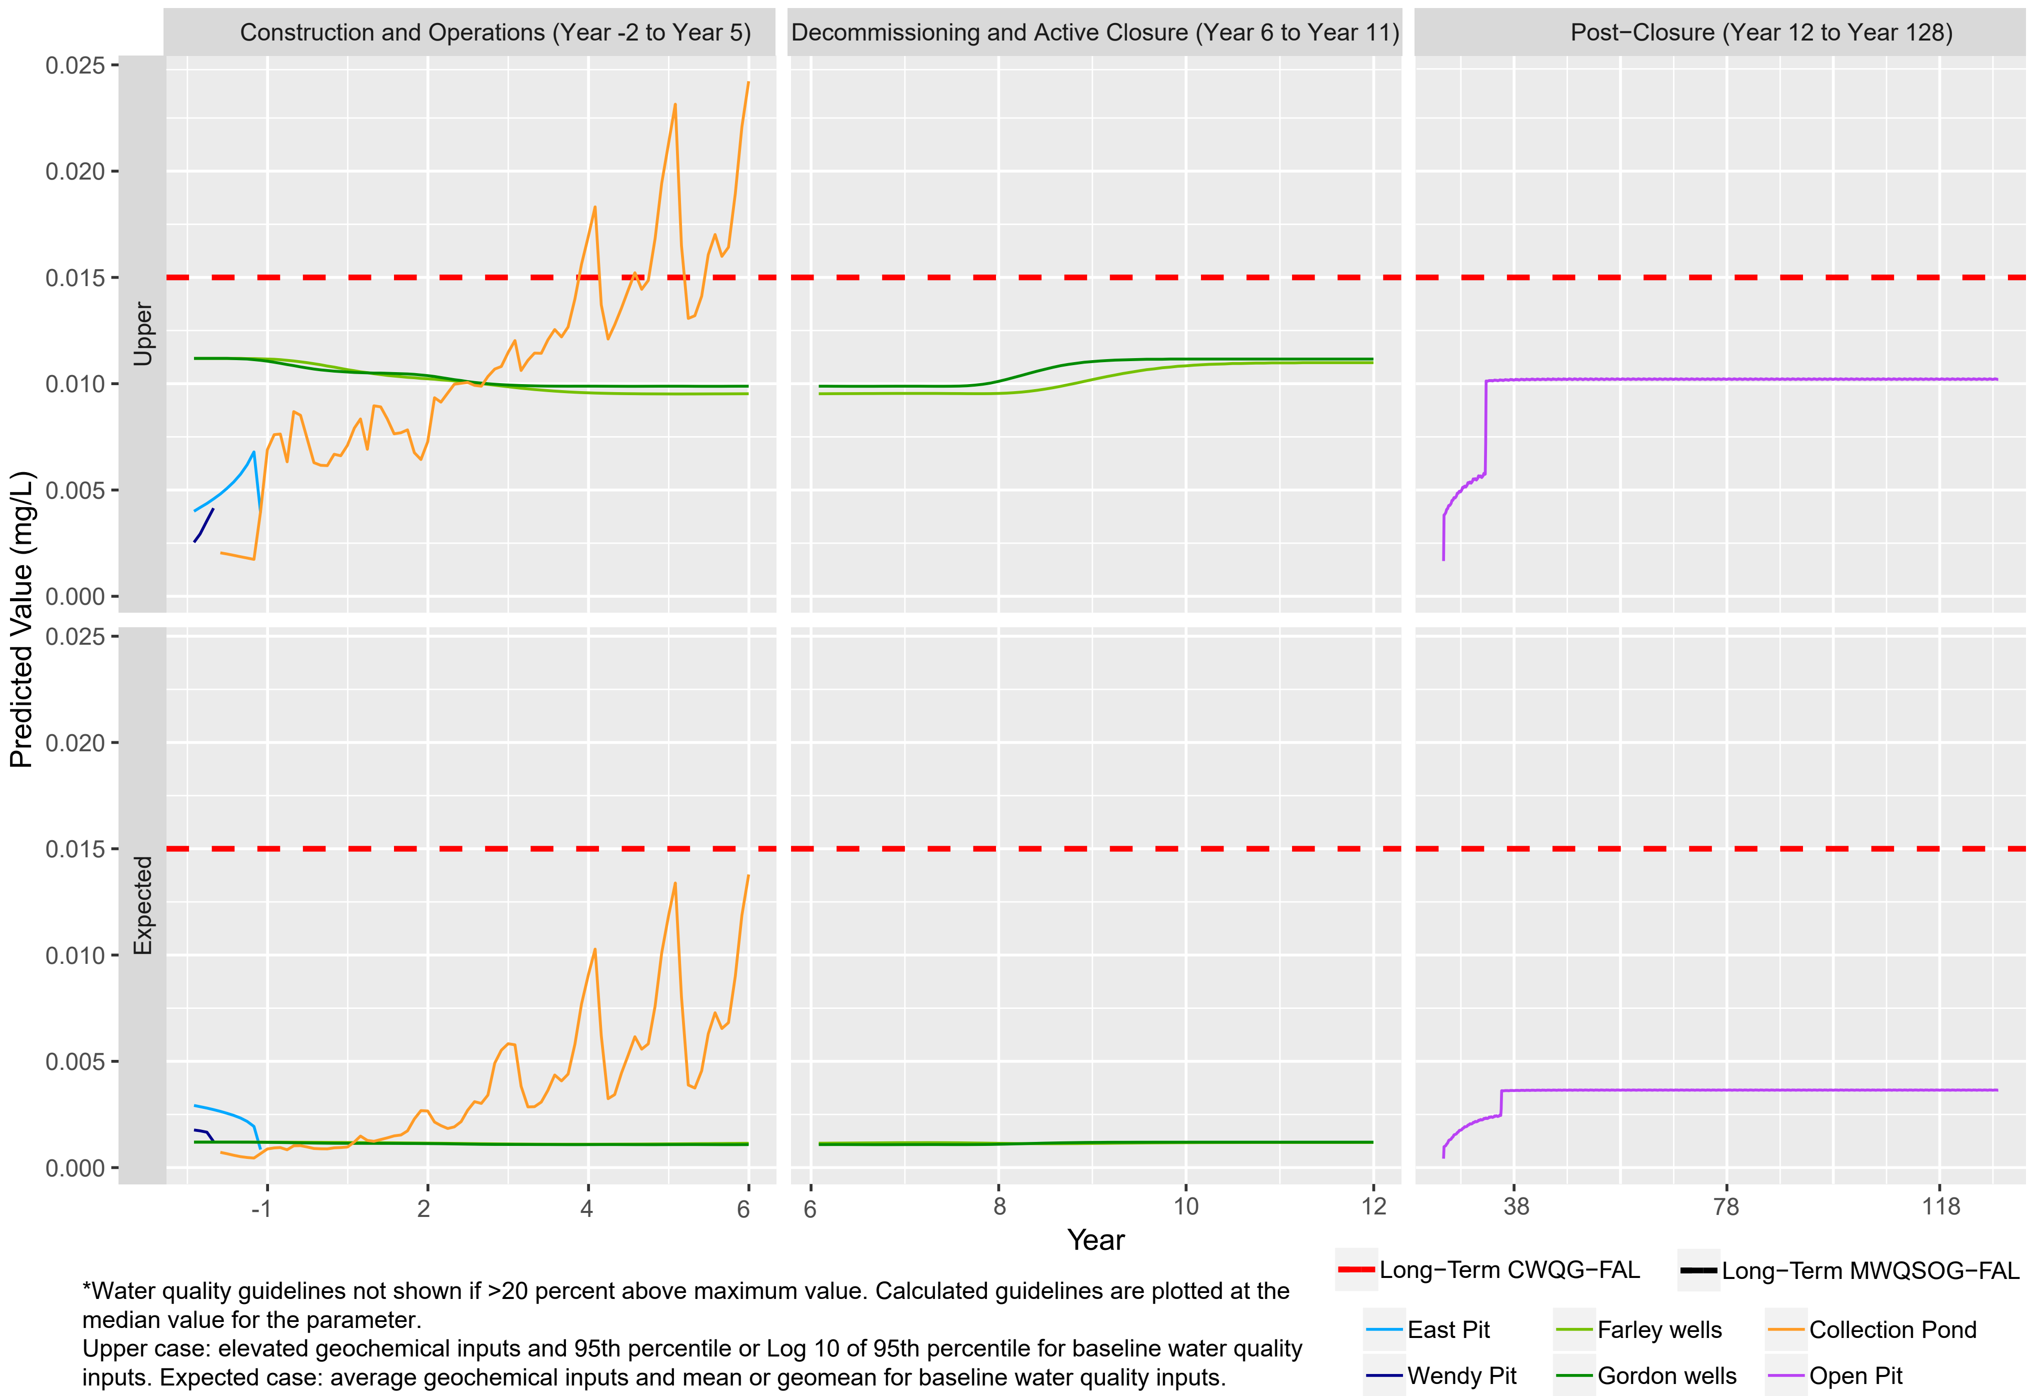
Unionized Ammonia (NH3), (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

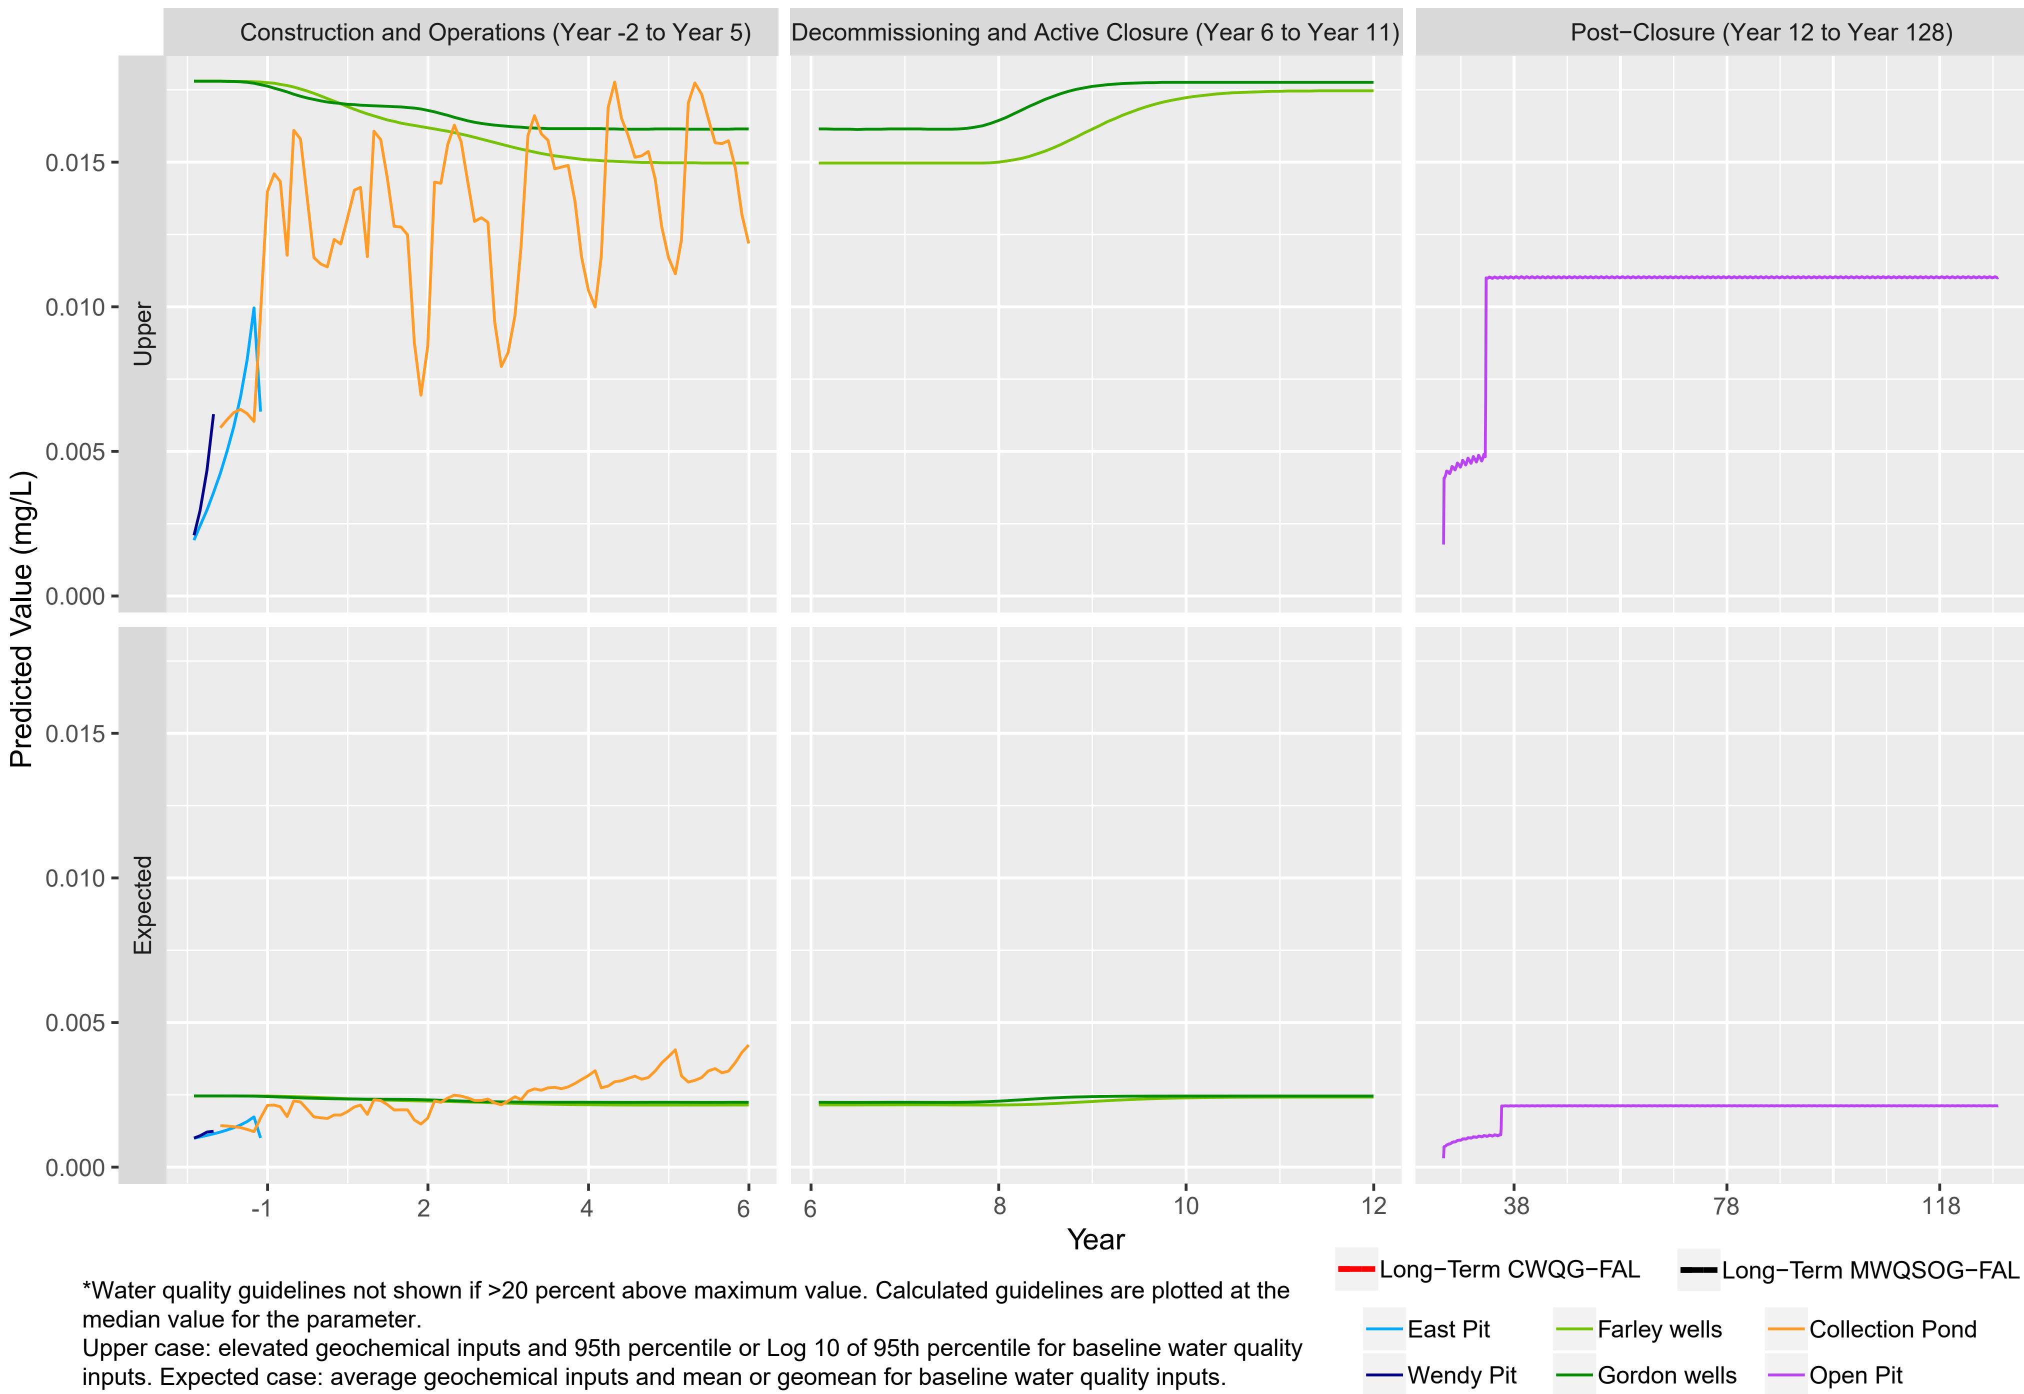
Uranium, Total (mg/L)



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-1: Gordon - Predicted Concentrations in Discharges

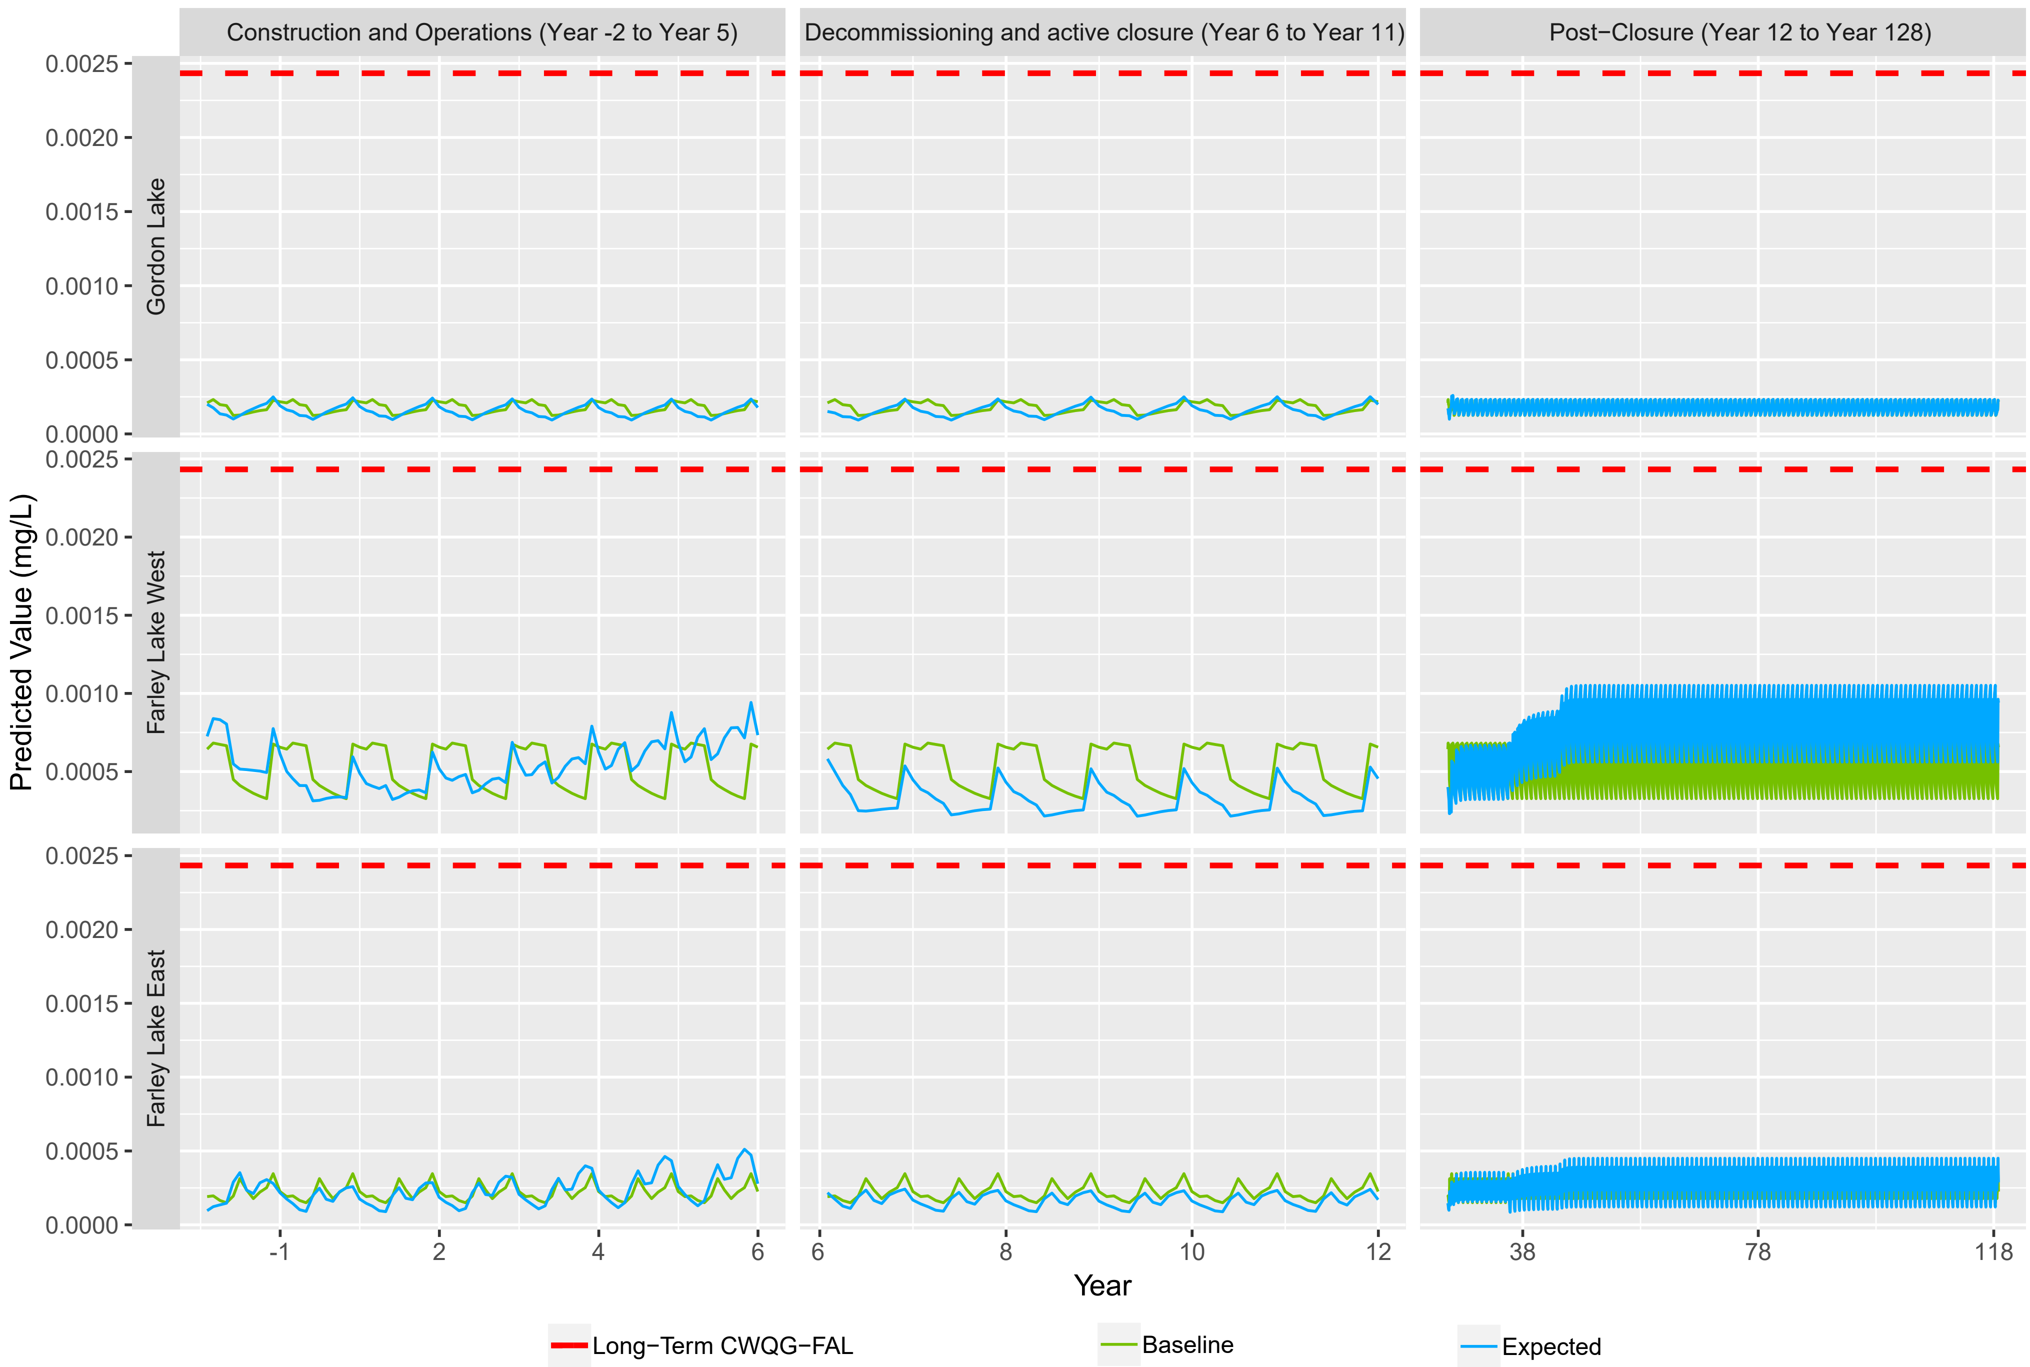
Zinc, Dissolved (mg/L)*



*Water quality guidelines not shown if >20 percent above maximum value. Calculated guidelines are plotted at the median value for the parameter.
Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs. Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.

Appendix I-2: Gordon - Predicted Concentrations in Receivers - Expected Case

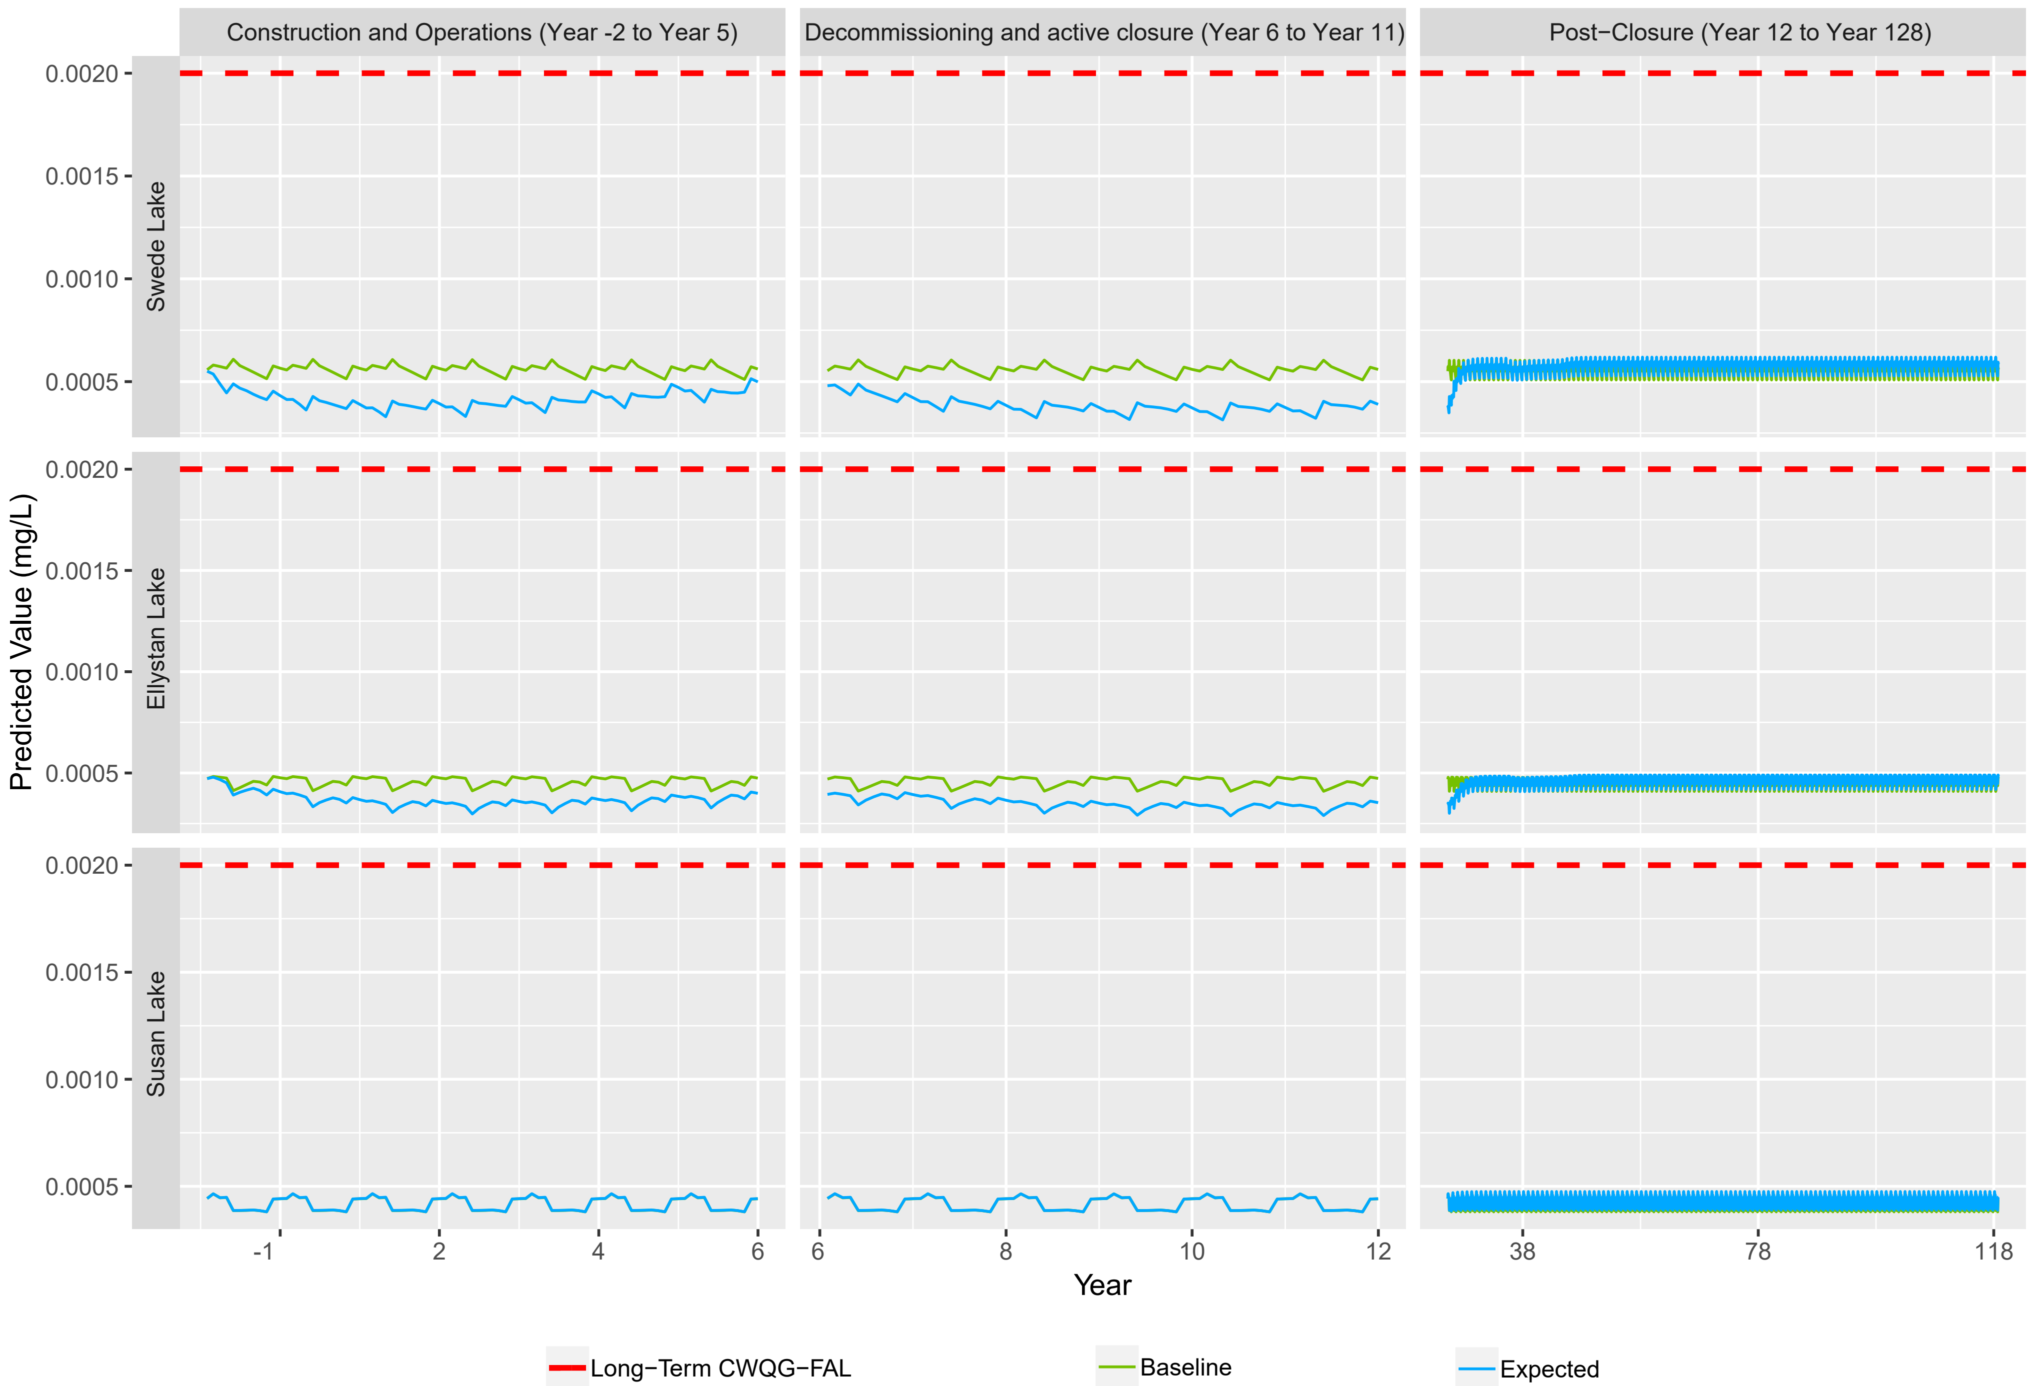
Copper, Total (mg/L)



Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-2: Gordon - Predicted Concentrations in Receivers - Expected Case

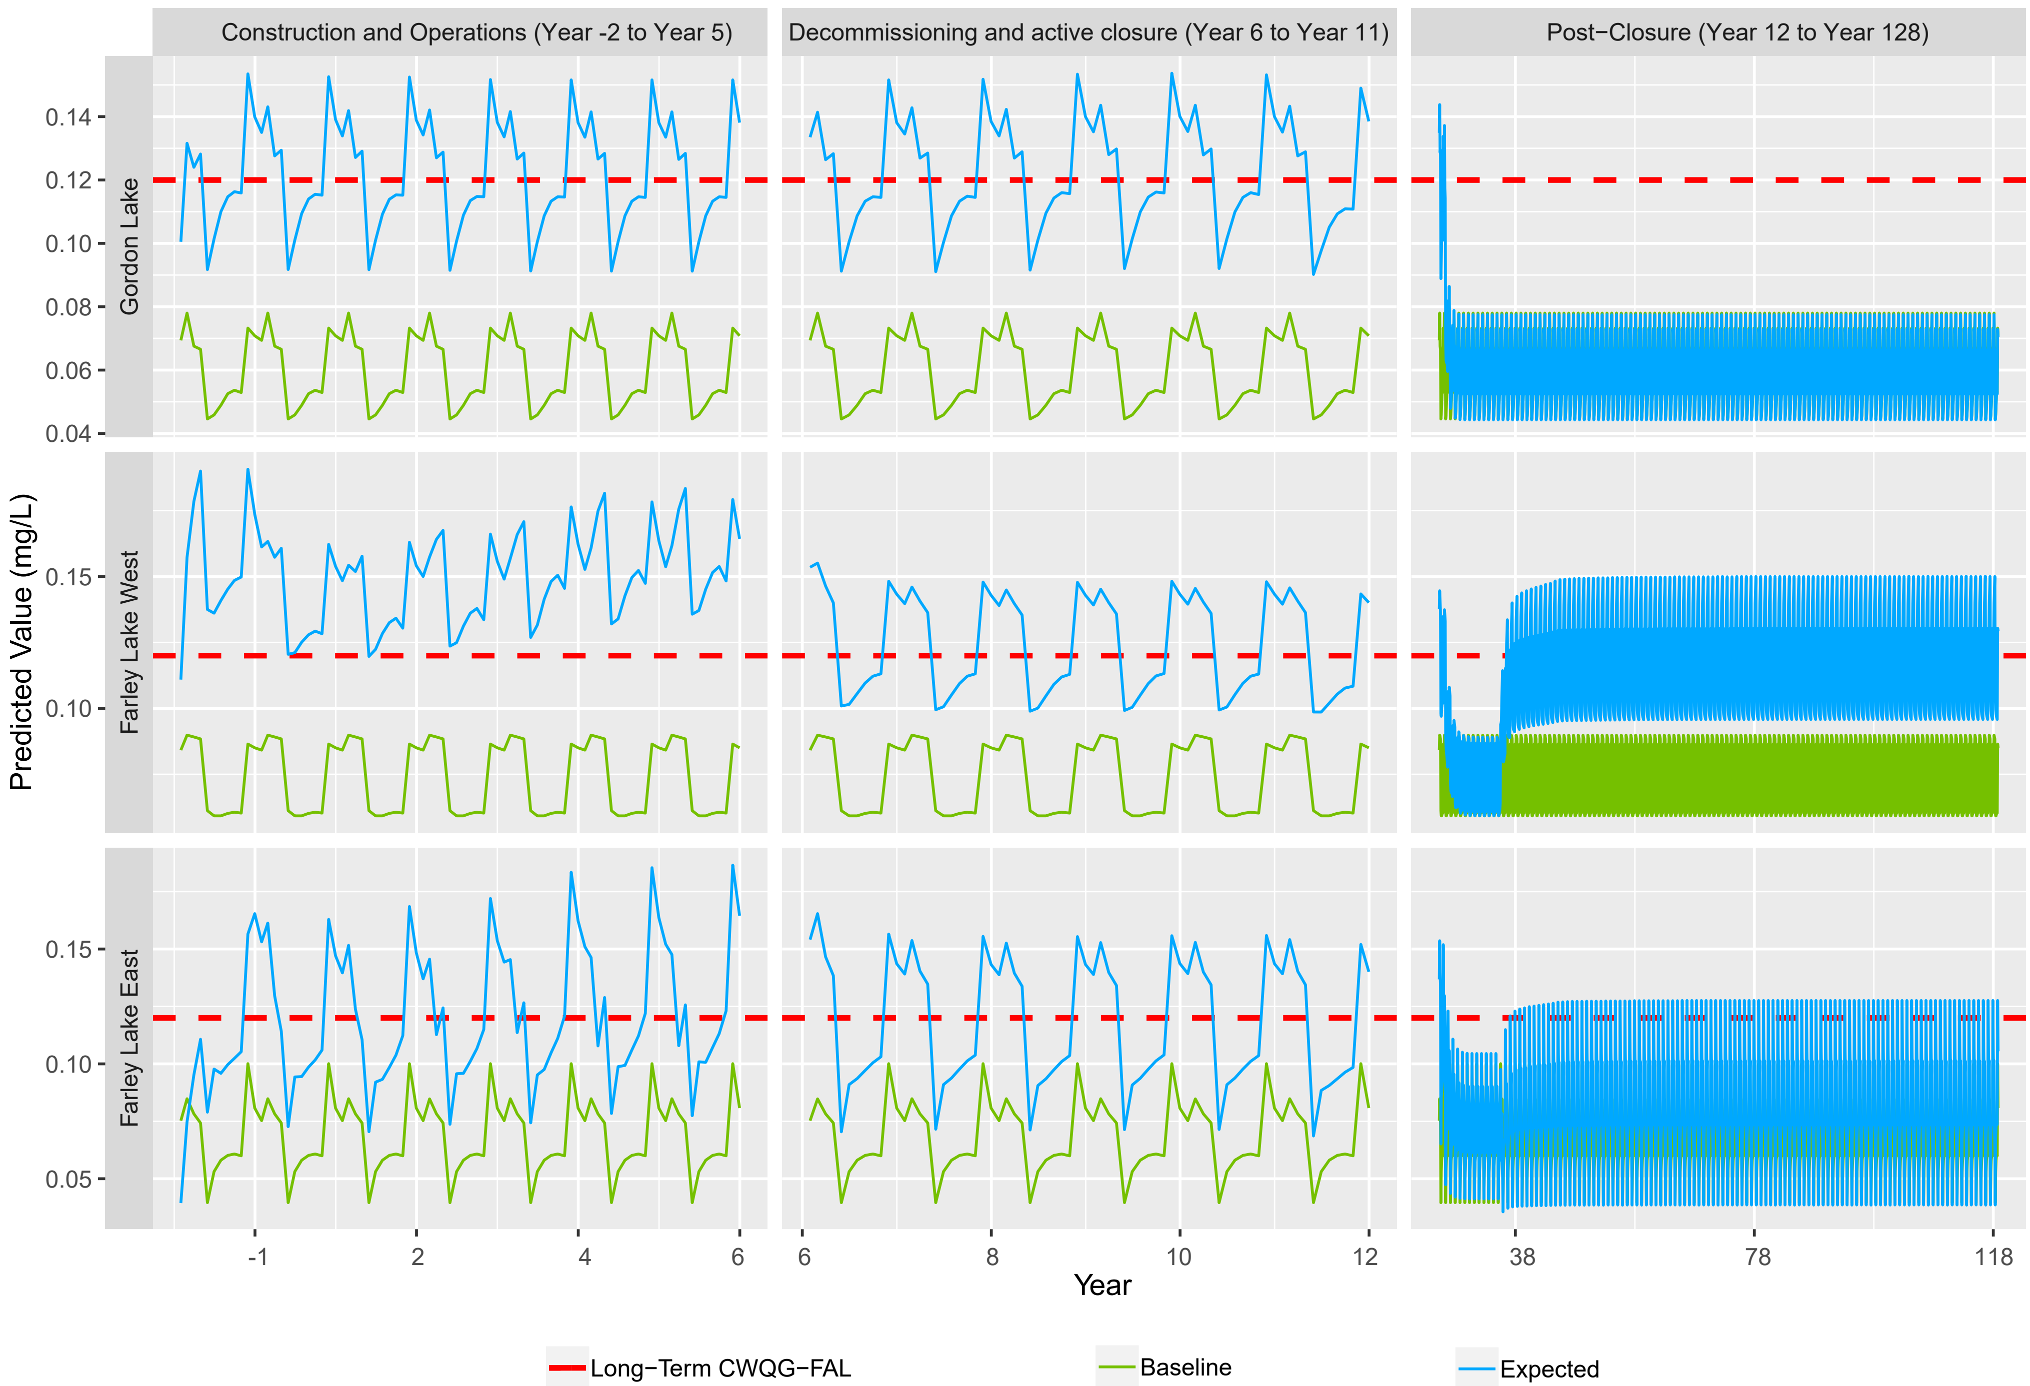
Copper, Total (mg/L)



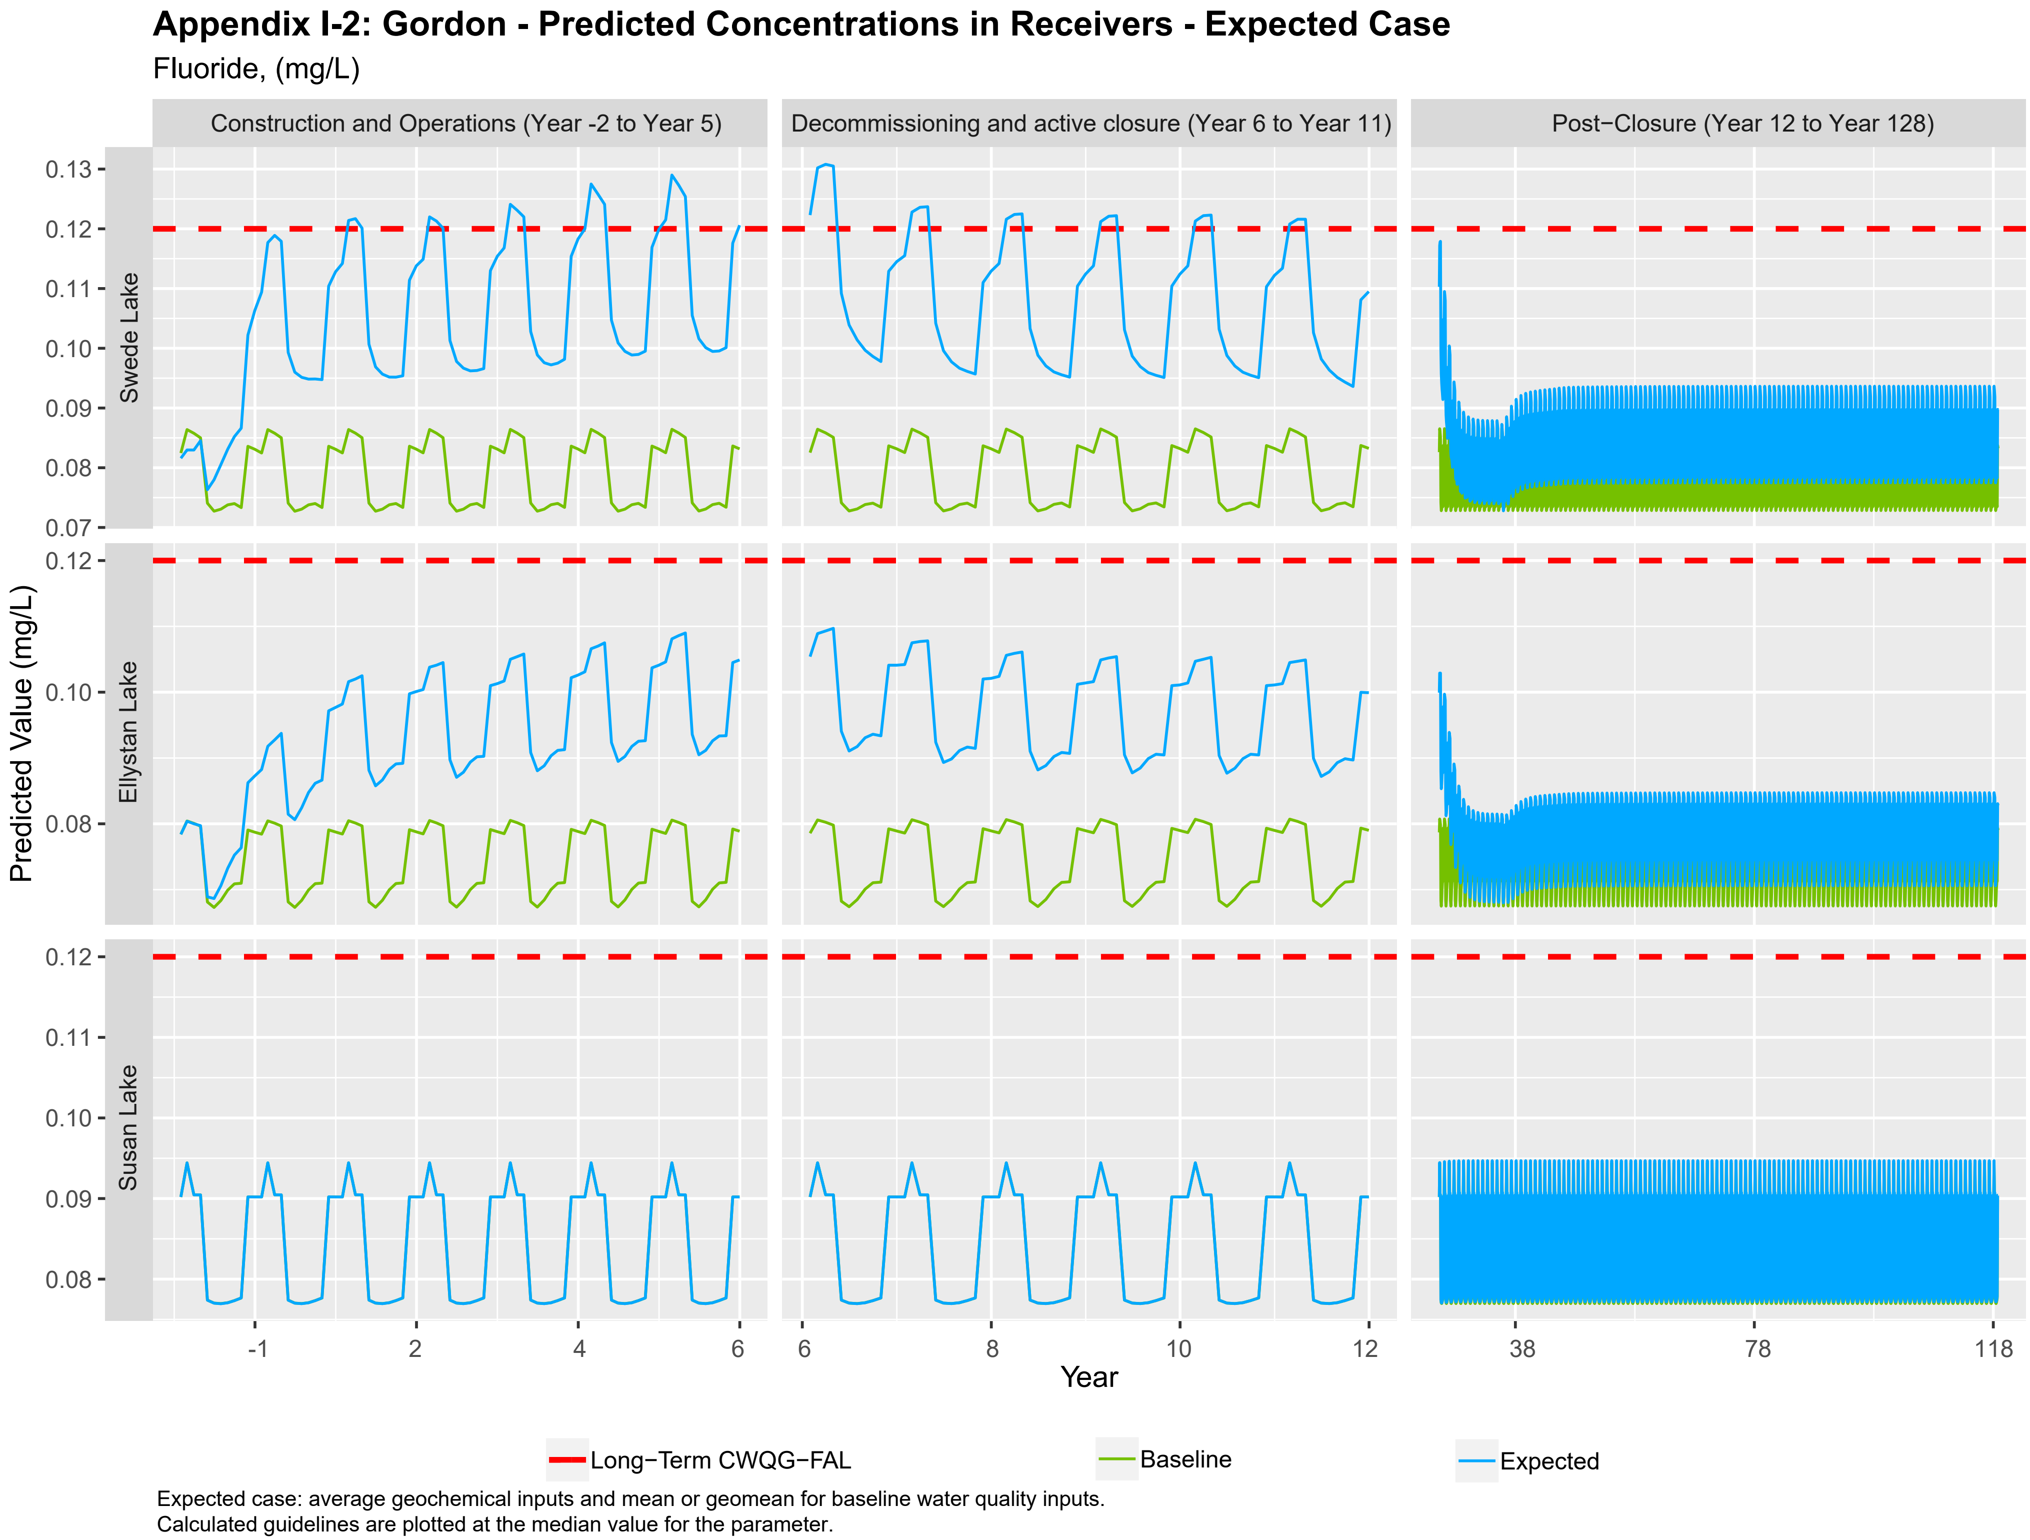
Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-2: Gordon - Predicted Concentrations in Receivers - Expected Case

Fluoride, (mg/L)



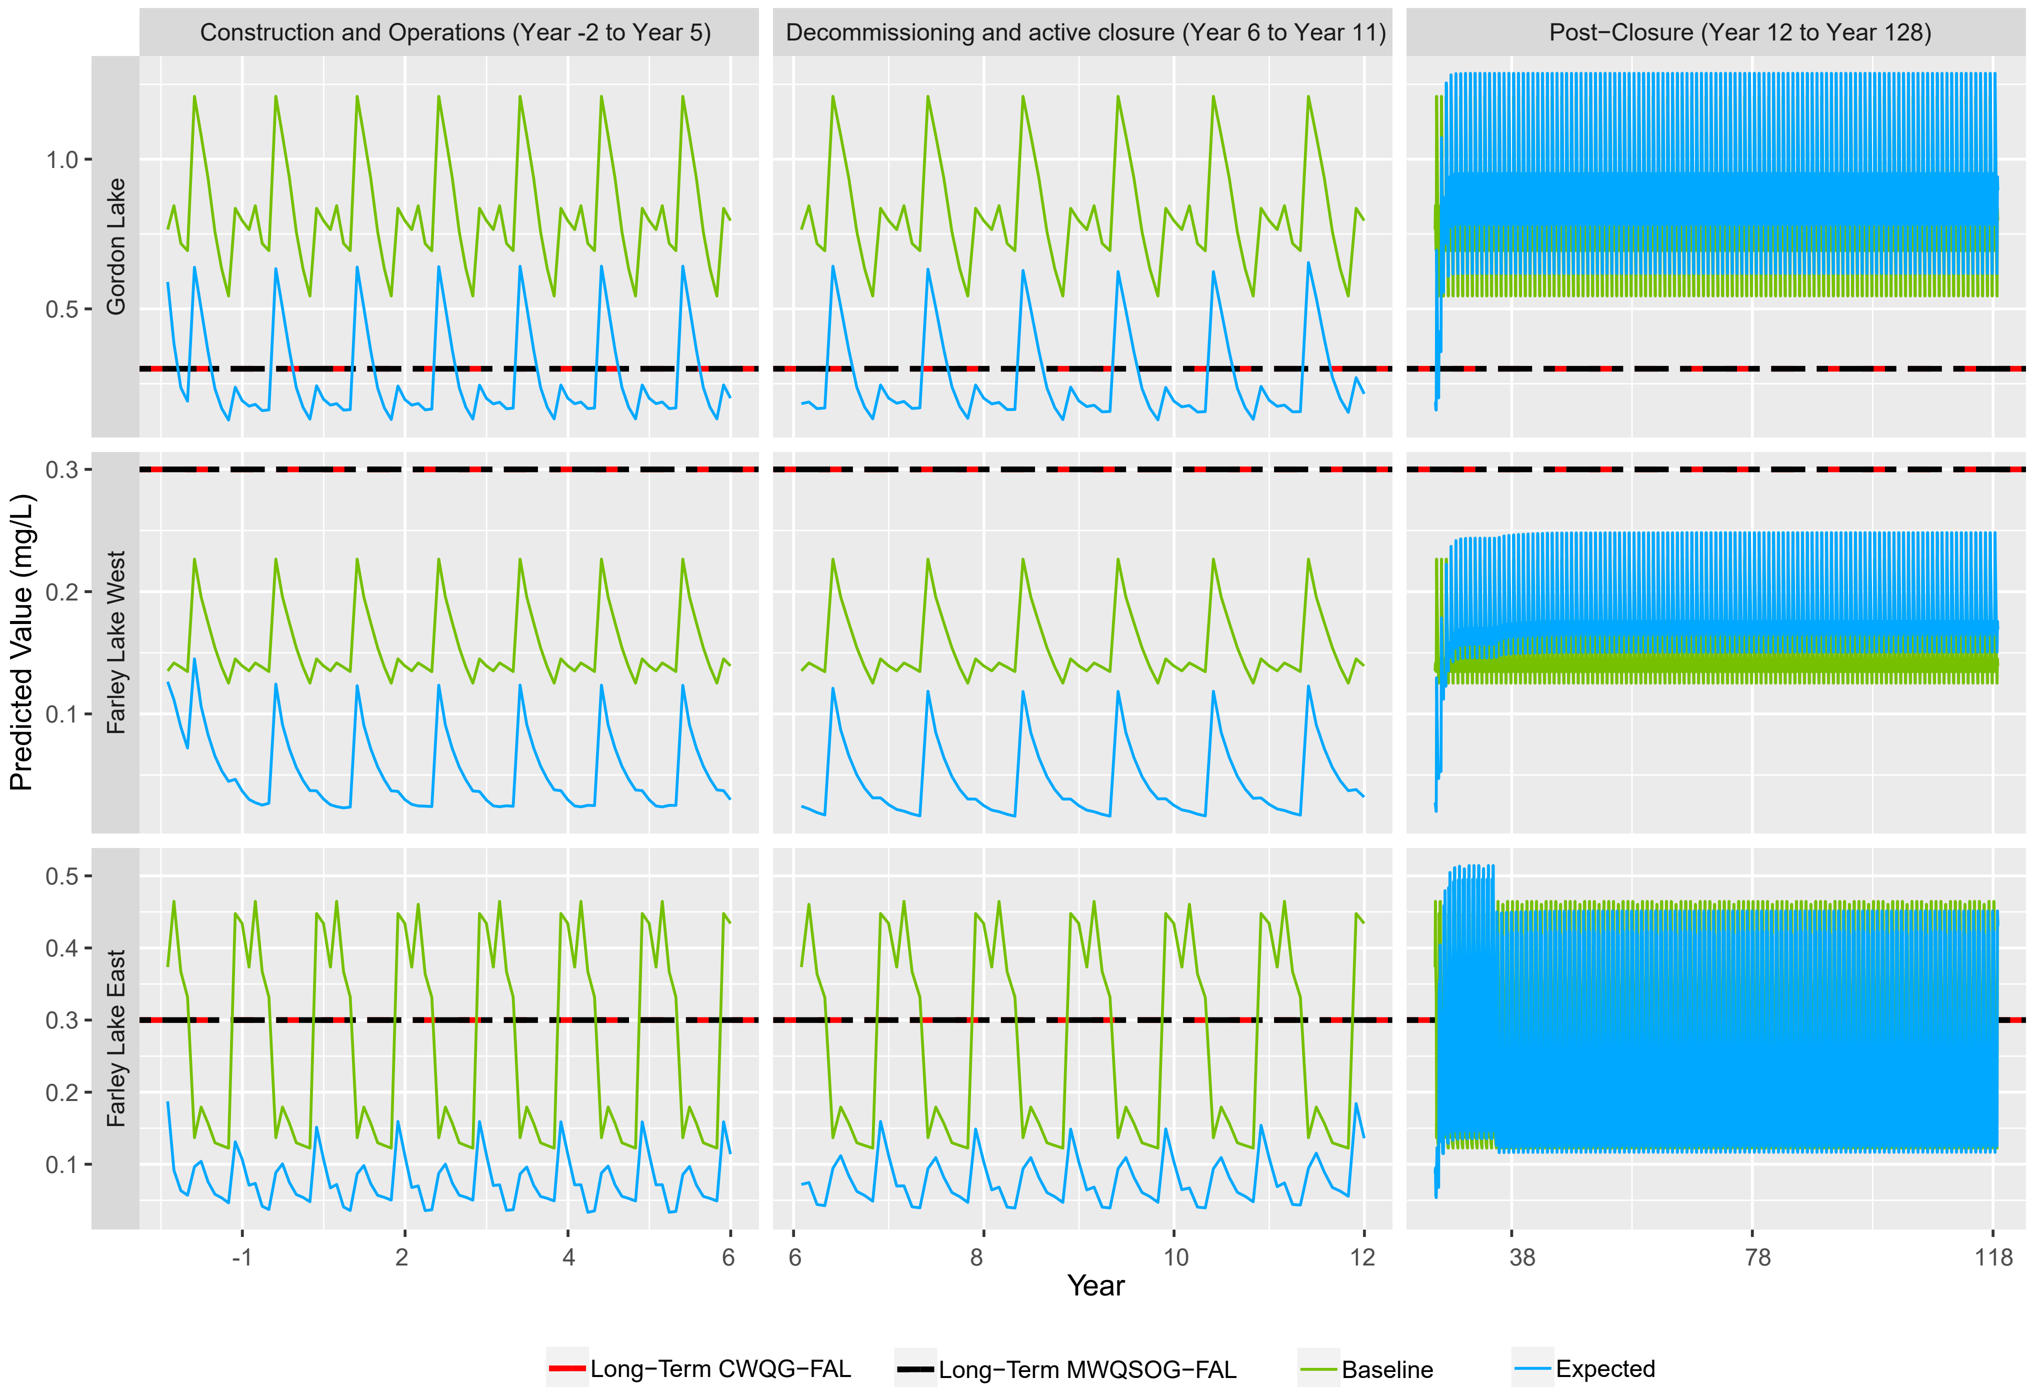
Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.



Appendix I-2: Gordon - Predicted Concentrations in Receivers - Expected Case
Fluoride, (mg/L)
Construction and Operations (Year -2 to Year 5)
Decommissioning and active closure (Year 6 to Year 11)
Post−Closure (Year 12 to Year 128)
Swede Lake
Ellystan Lake
Susan Lake
Predicted Value (mg/L)
Year
Long−Term CWQG−FAL
Baseline
Expected
Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-2: Gordon - Predicted Concentrations in Receivers - Expected Case

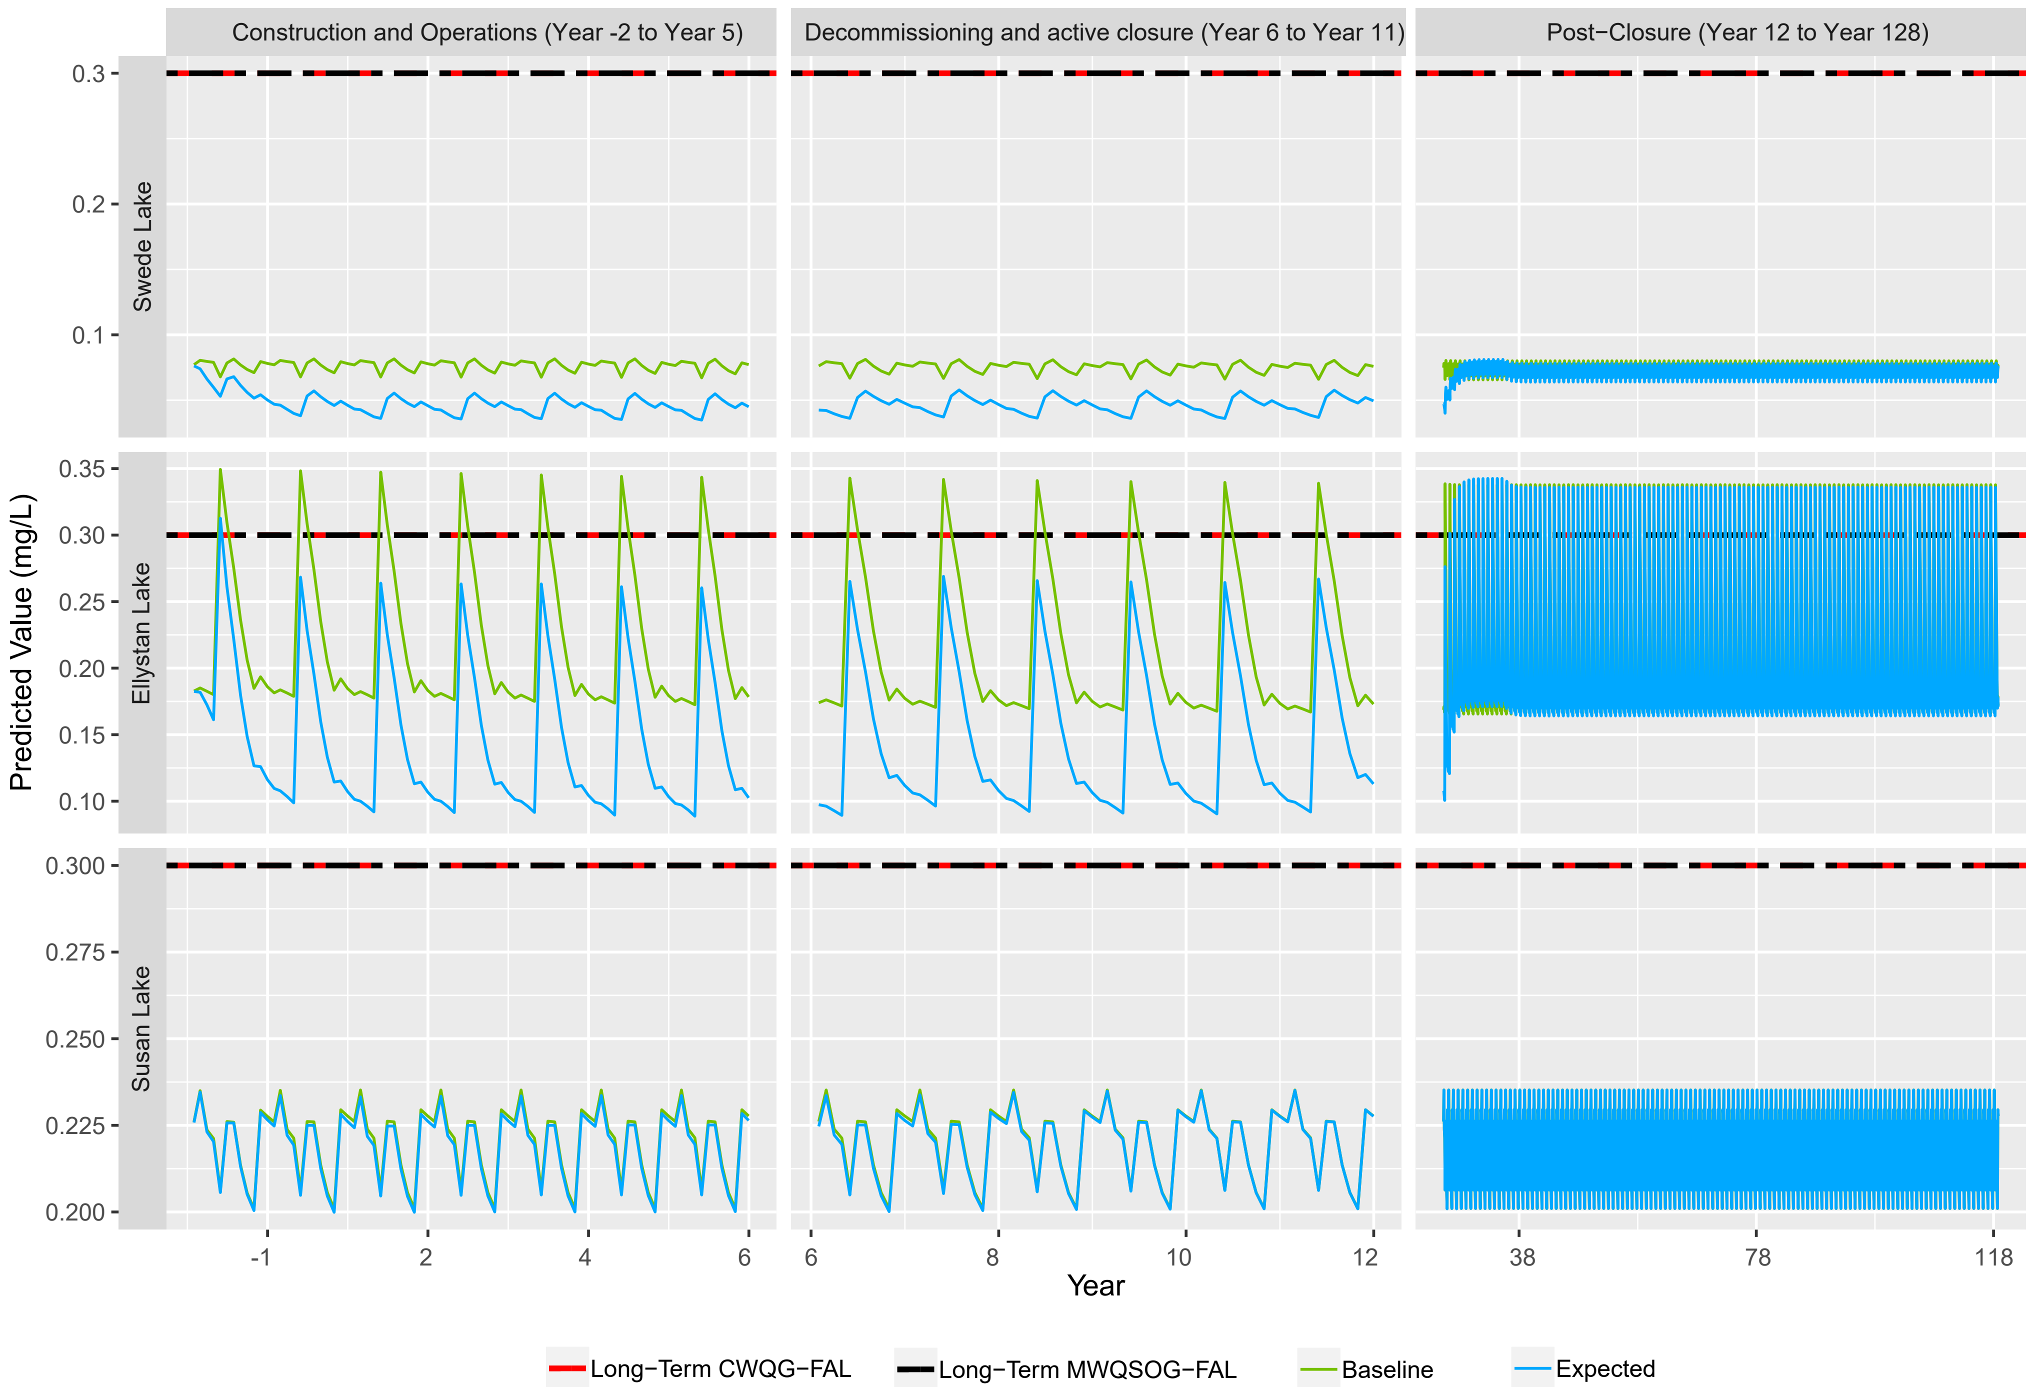
Iron, Total (mg/L)



Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-2: Gordon - Predicted Concentrations in Receivers - Expected Case

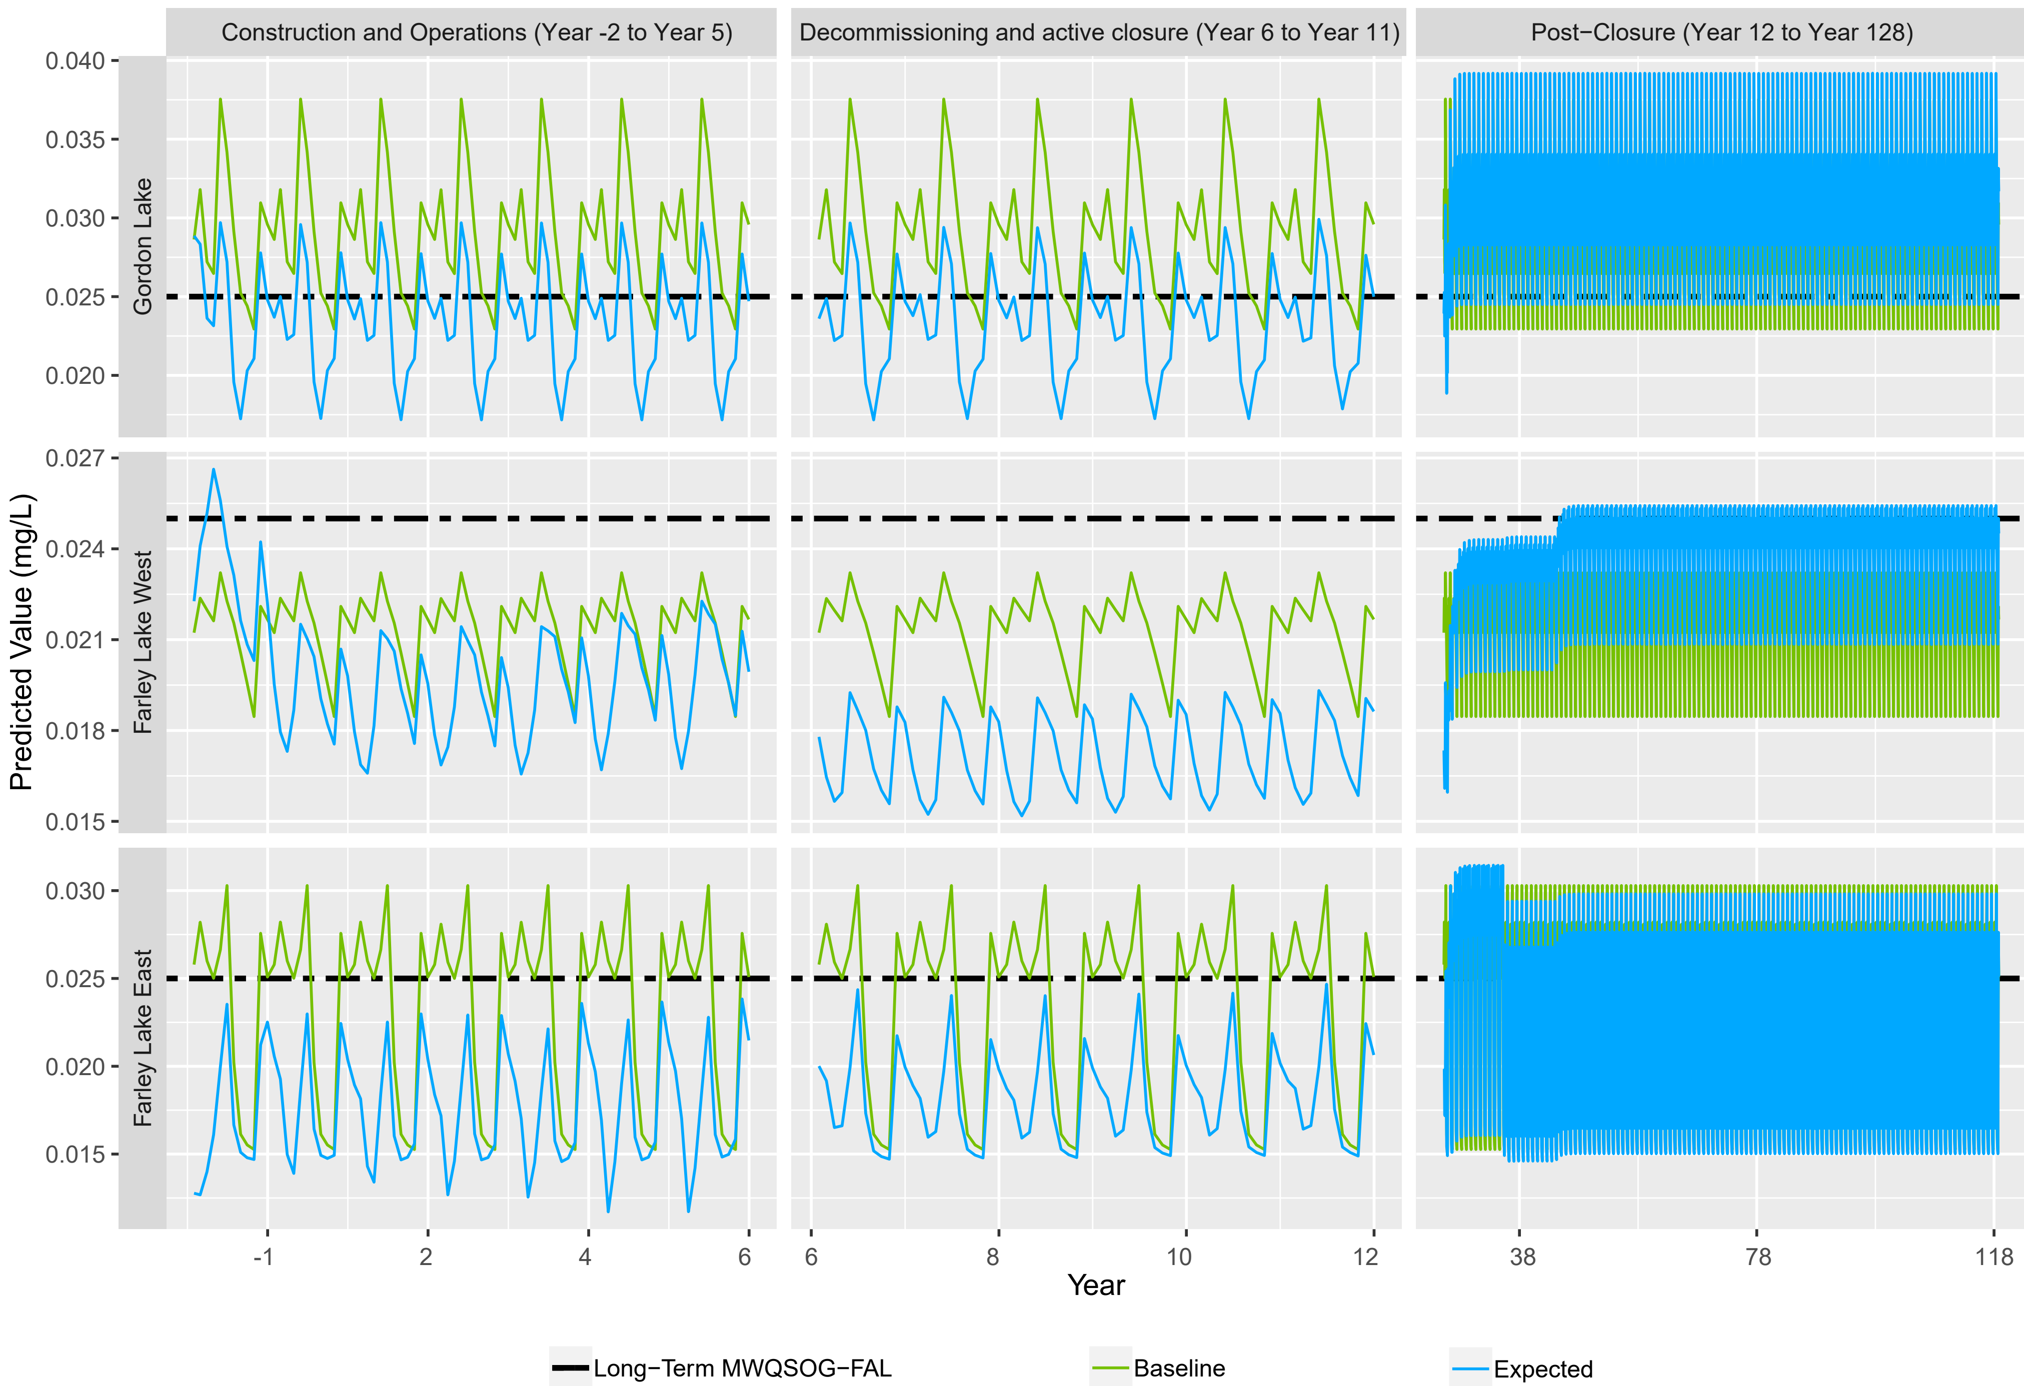
Iron, Total (mg/L)



Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-2: Gordon - Predicted Concentrations in Receivers - Expected Case

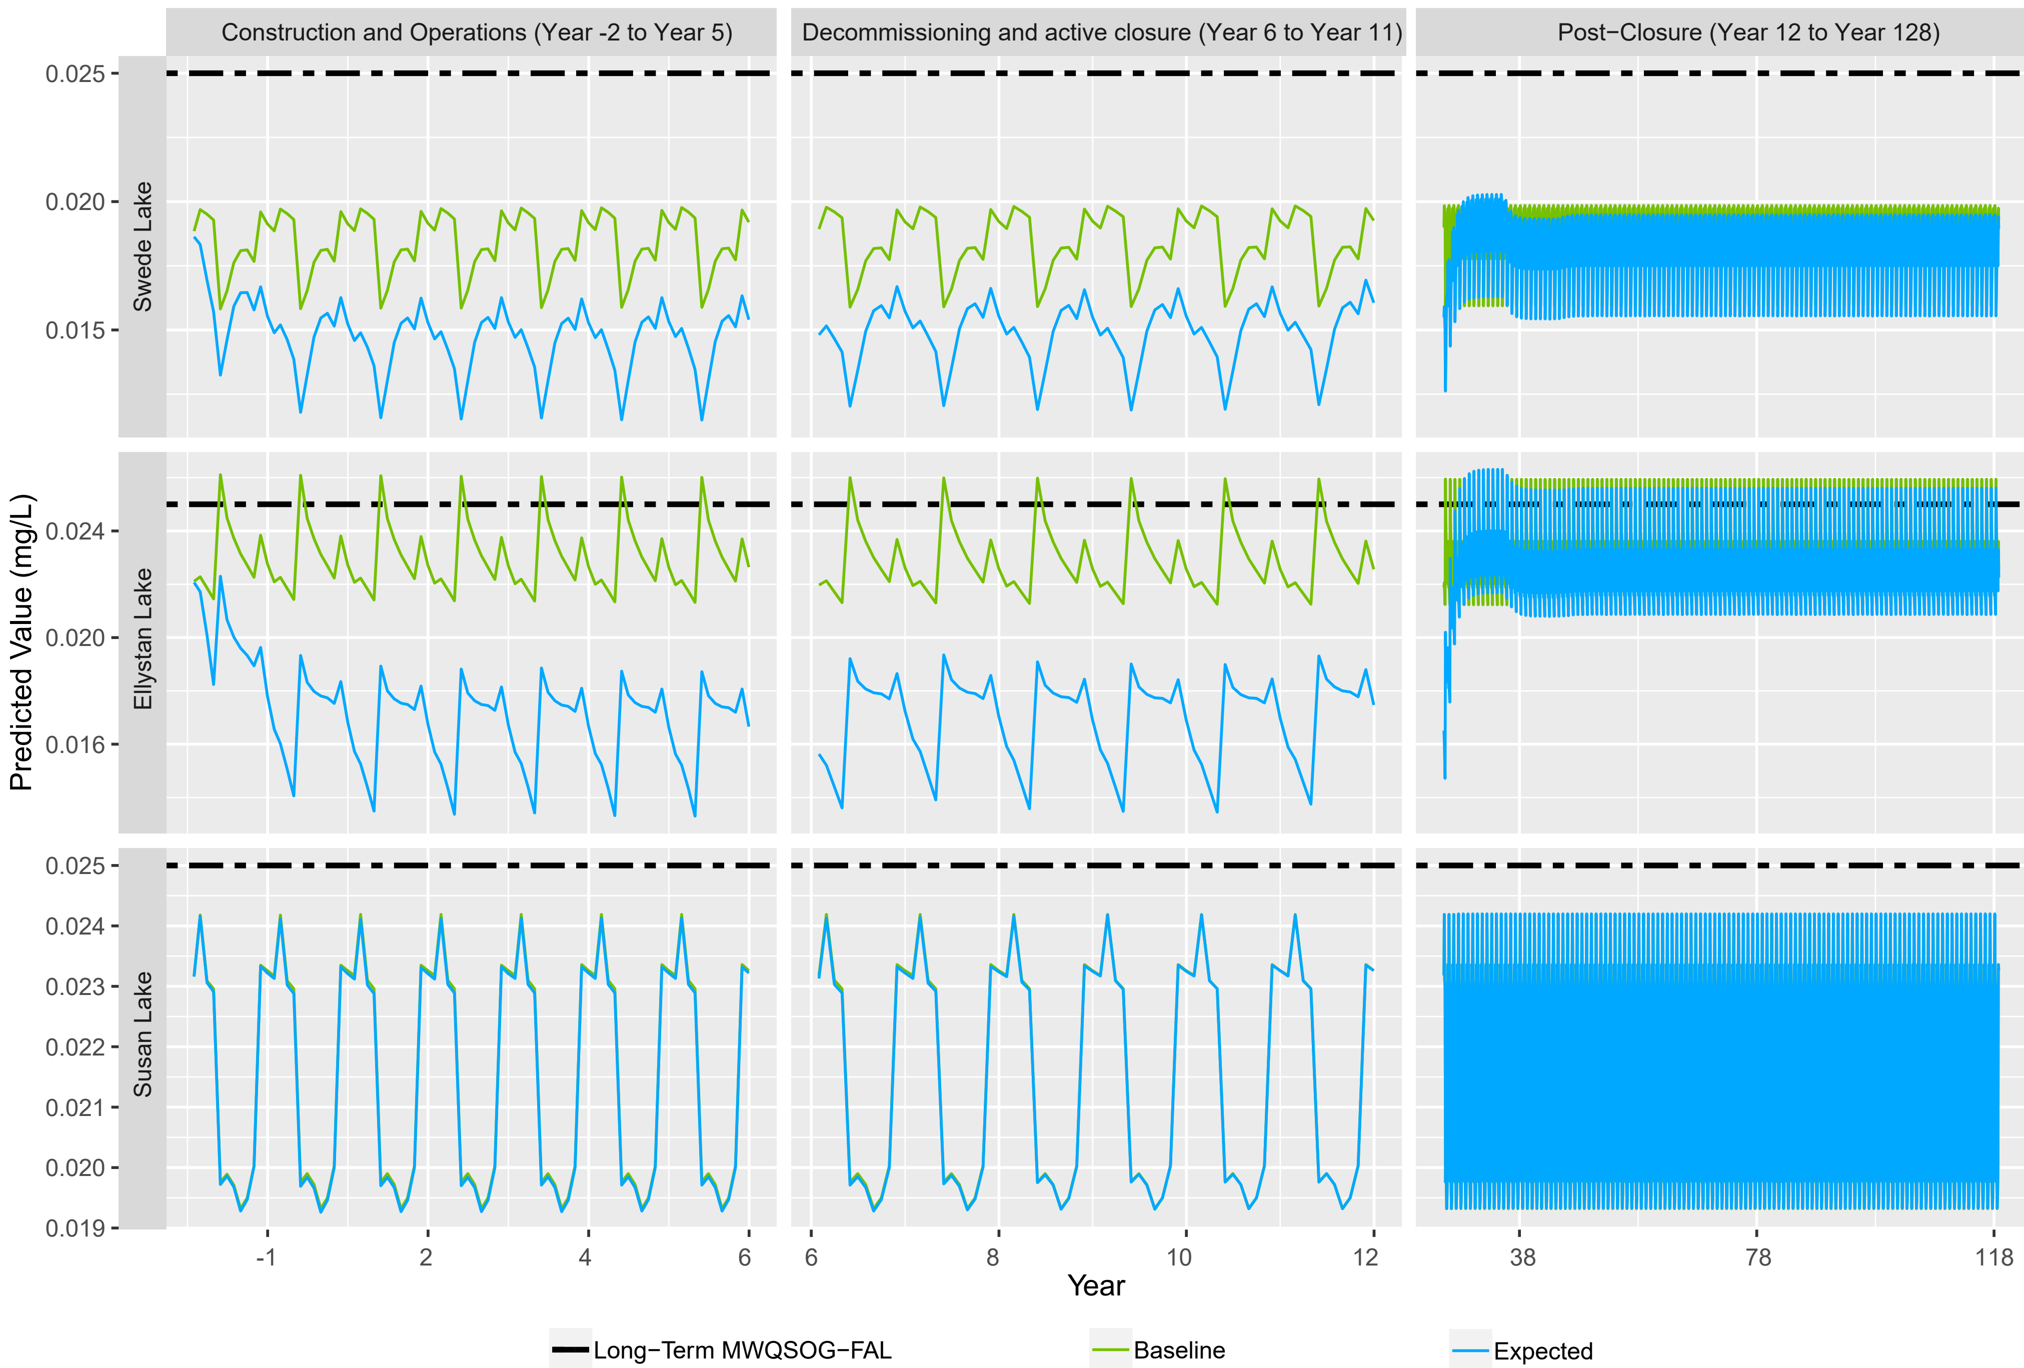
Phosphorus, Total, (mg/L)



Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-2: Gordon - Predicted Concentrations in Receivers - Expected Case

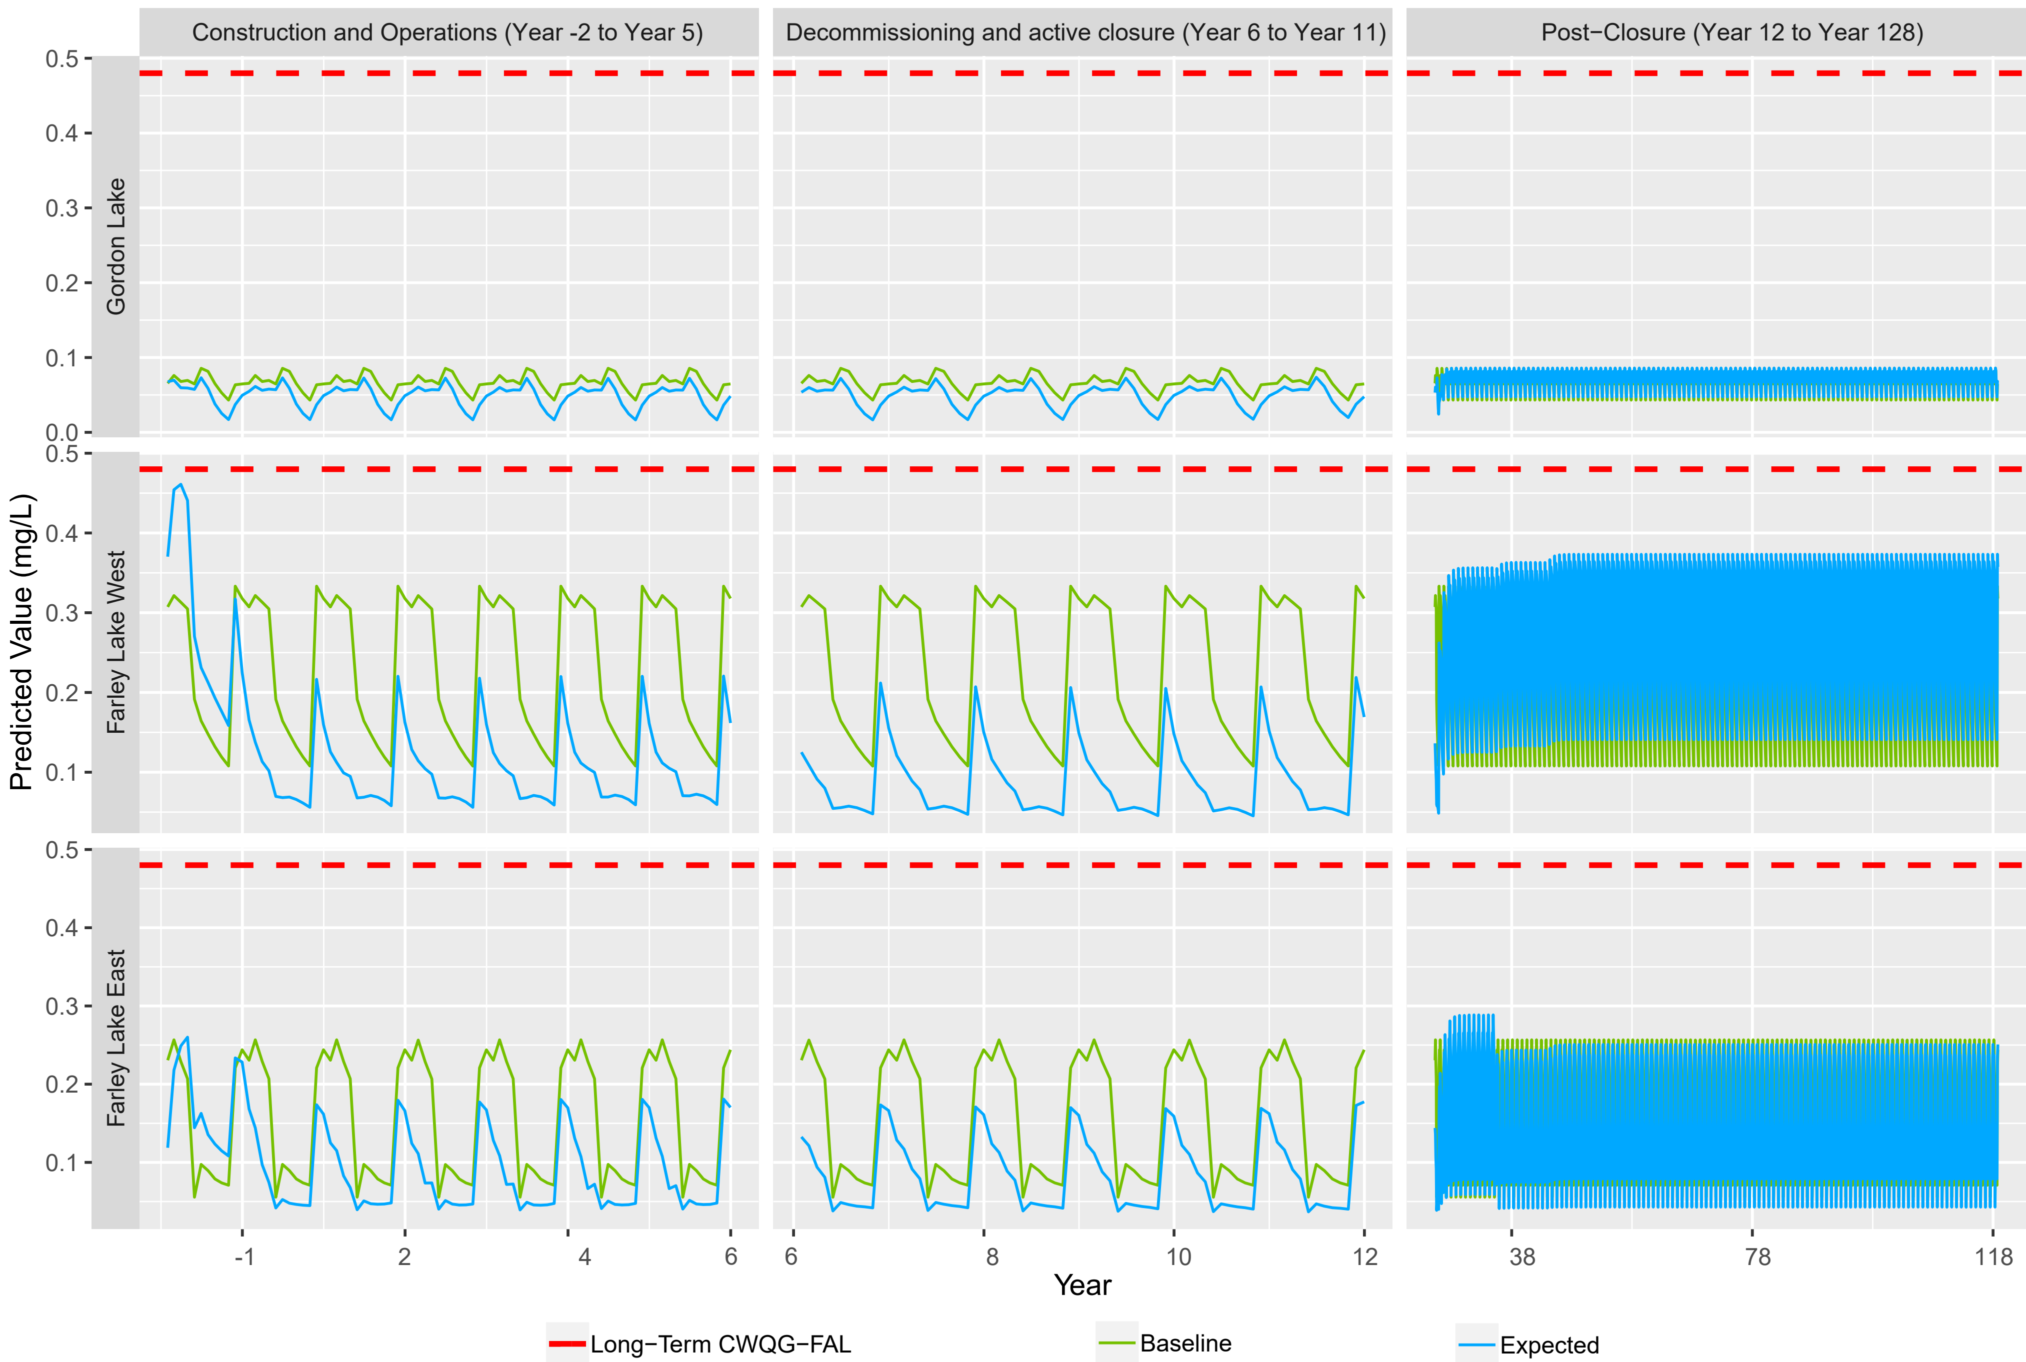
Phosphorus, Total, (mg/L)



Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-2: Gordon - Predicted Concentrations in Receivers - Expected Case

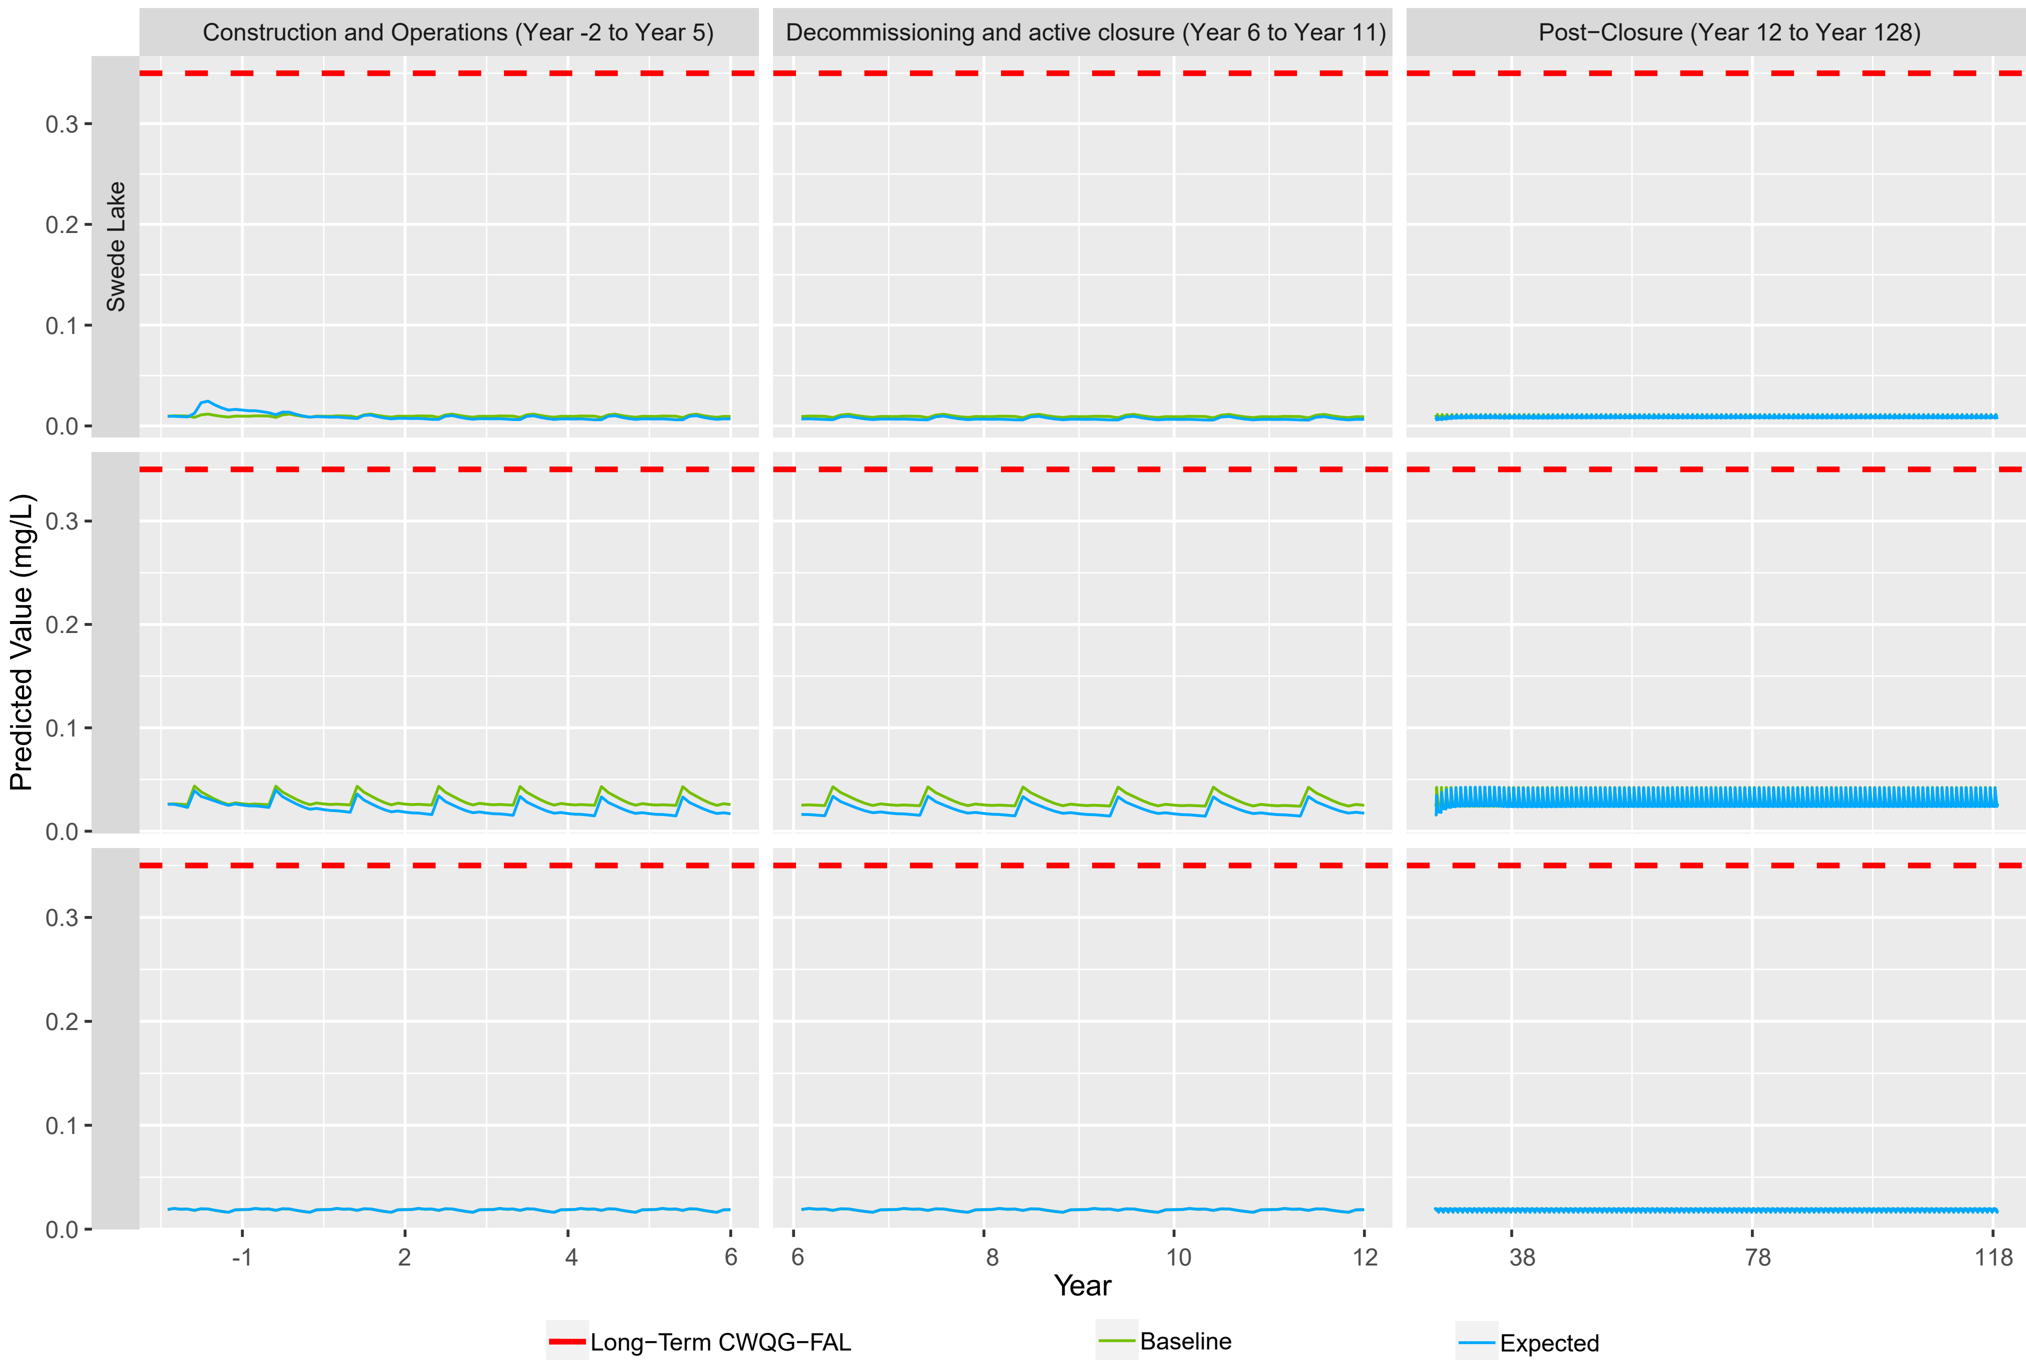
Manganese, Dissolved (mg/L)



Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-2: Gordon - Predicted Concentrations in Receivers - Expected Case

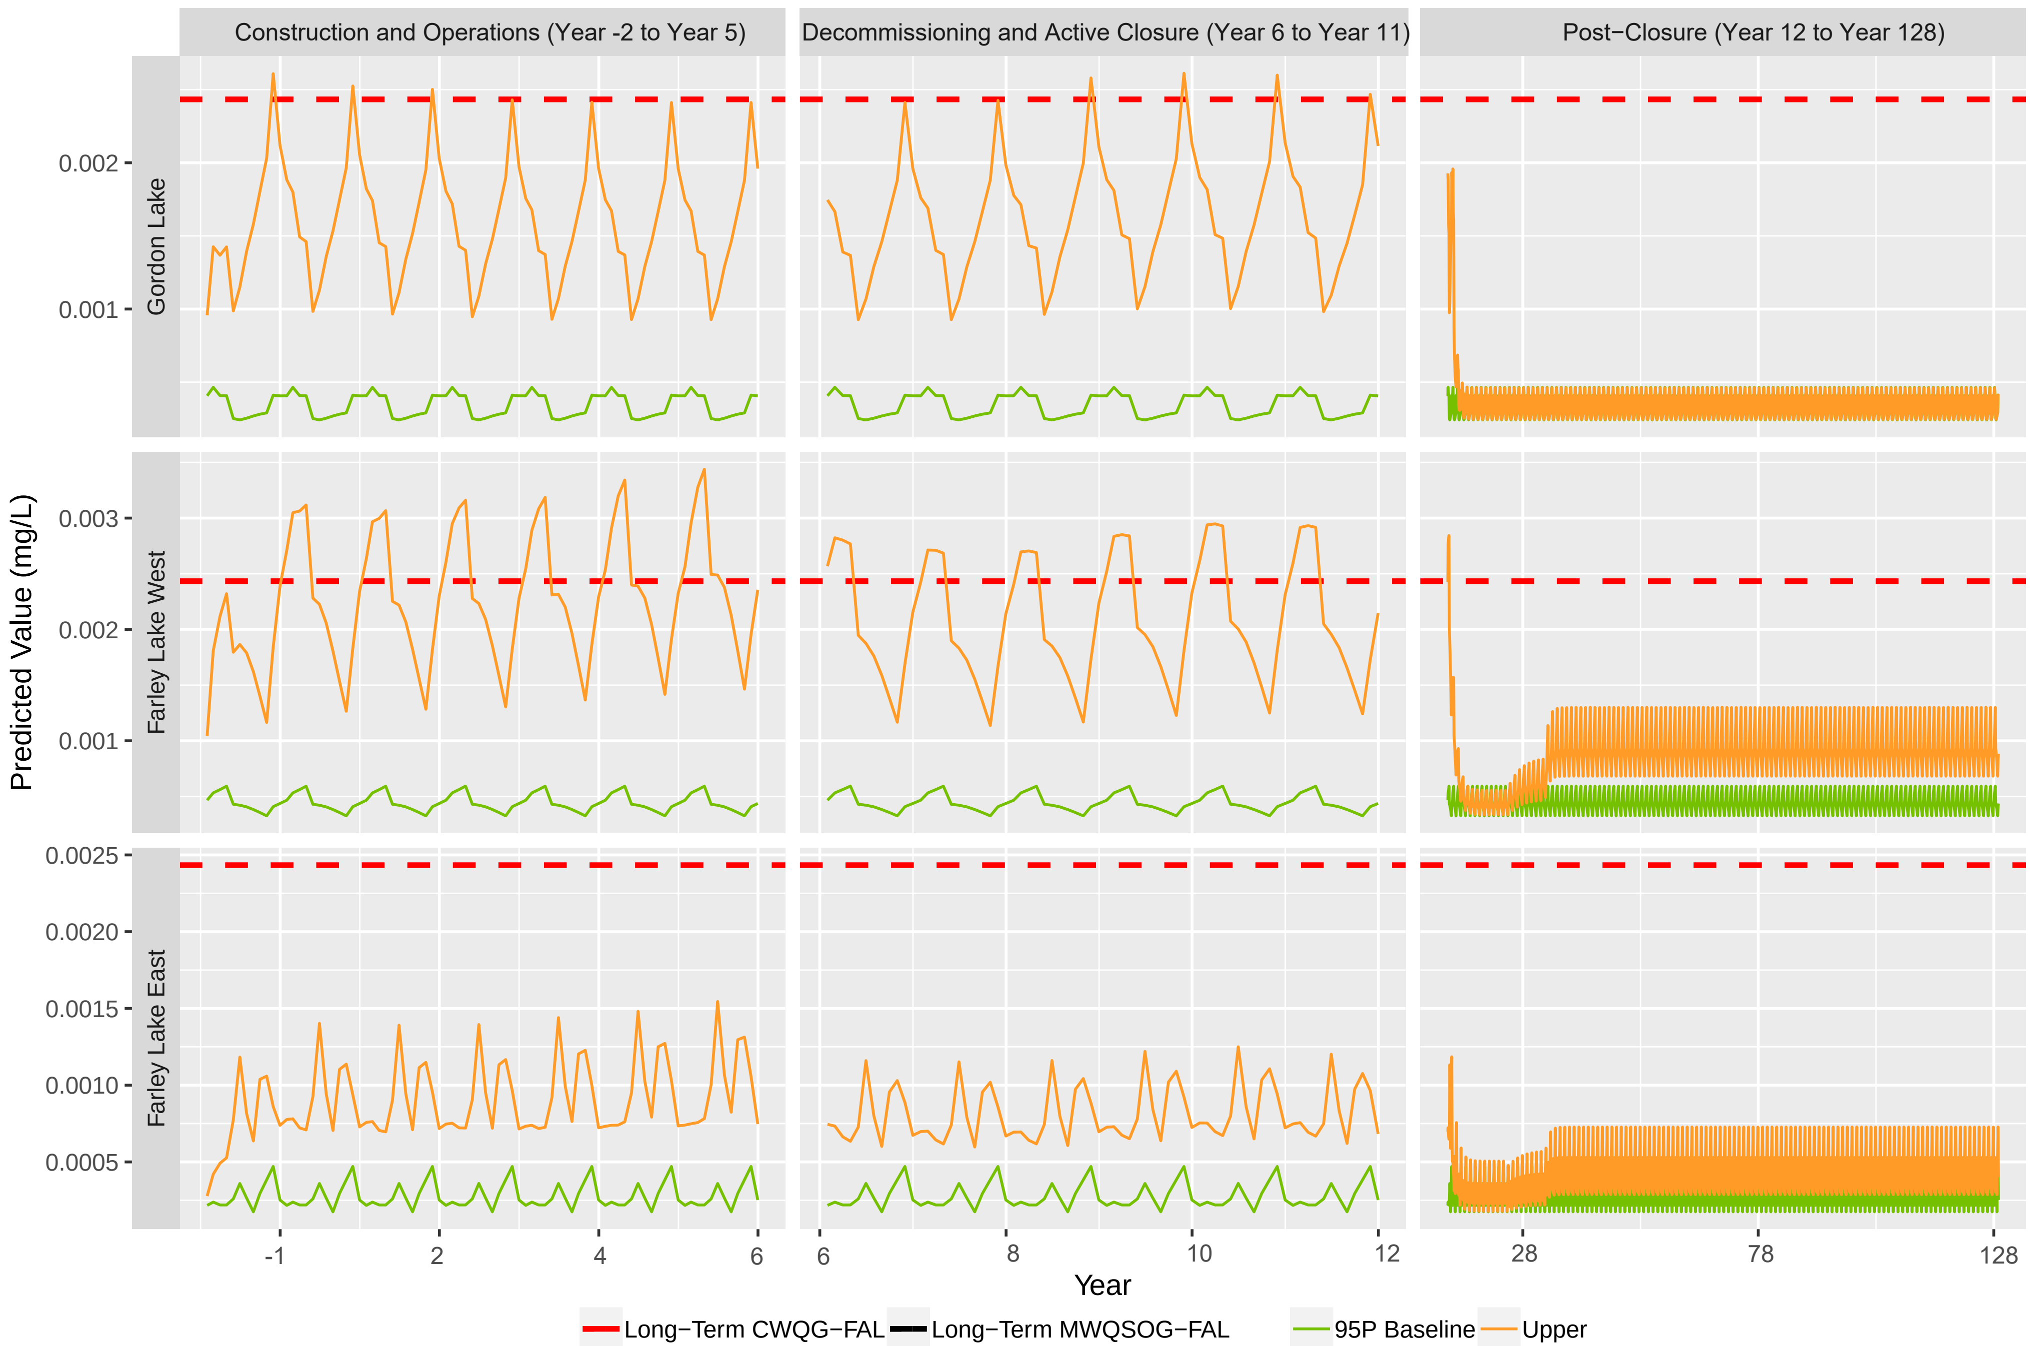
Manganese, Dissolved (mg/L)



Expected case: average geochemical inputs and mean or geomean for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-3: Gordon - Predicted Concentrations in Receivers - Upper Case

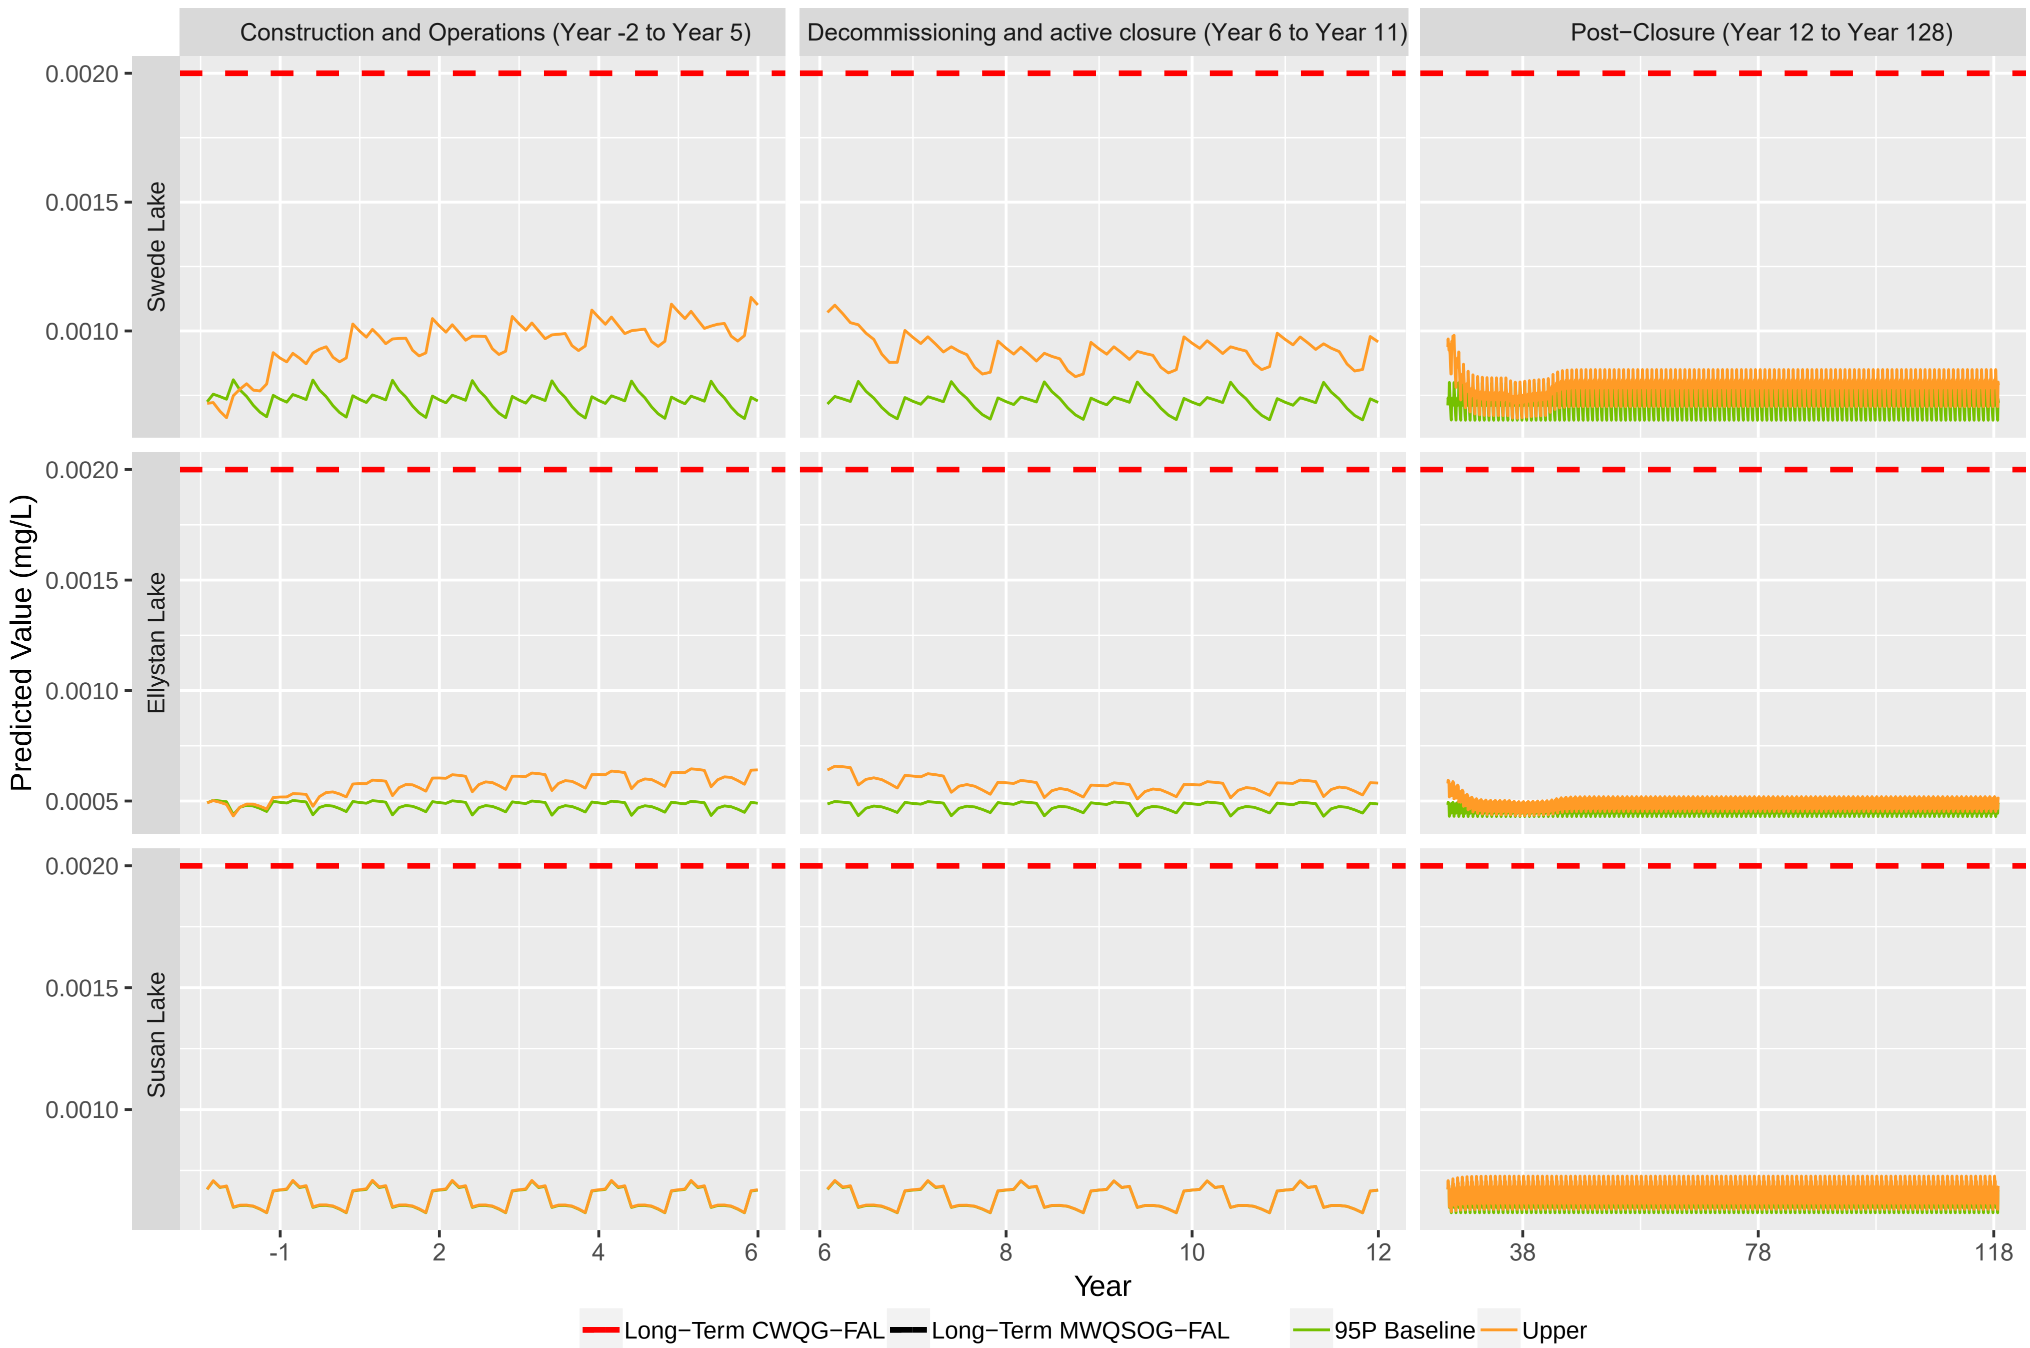
Copper, Total (mg/L)



Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-3: Gordon - Predicted Concentrations in Receivers - Upper Case

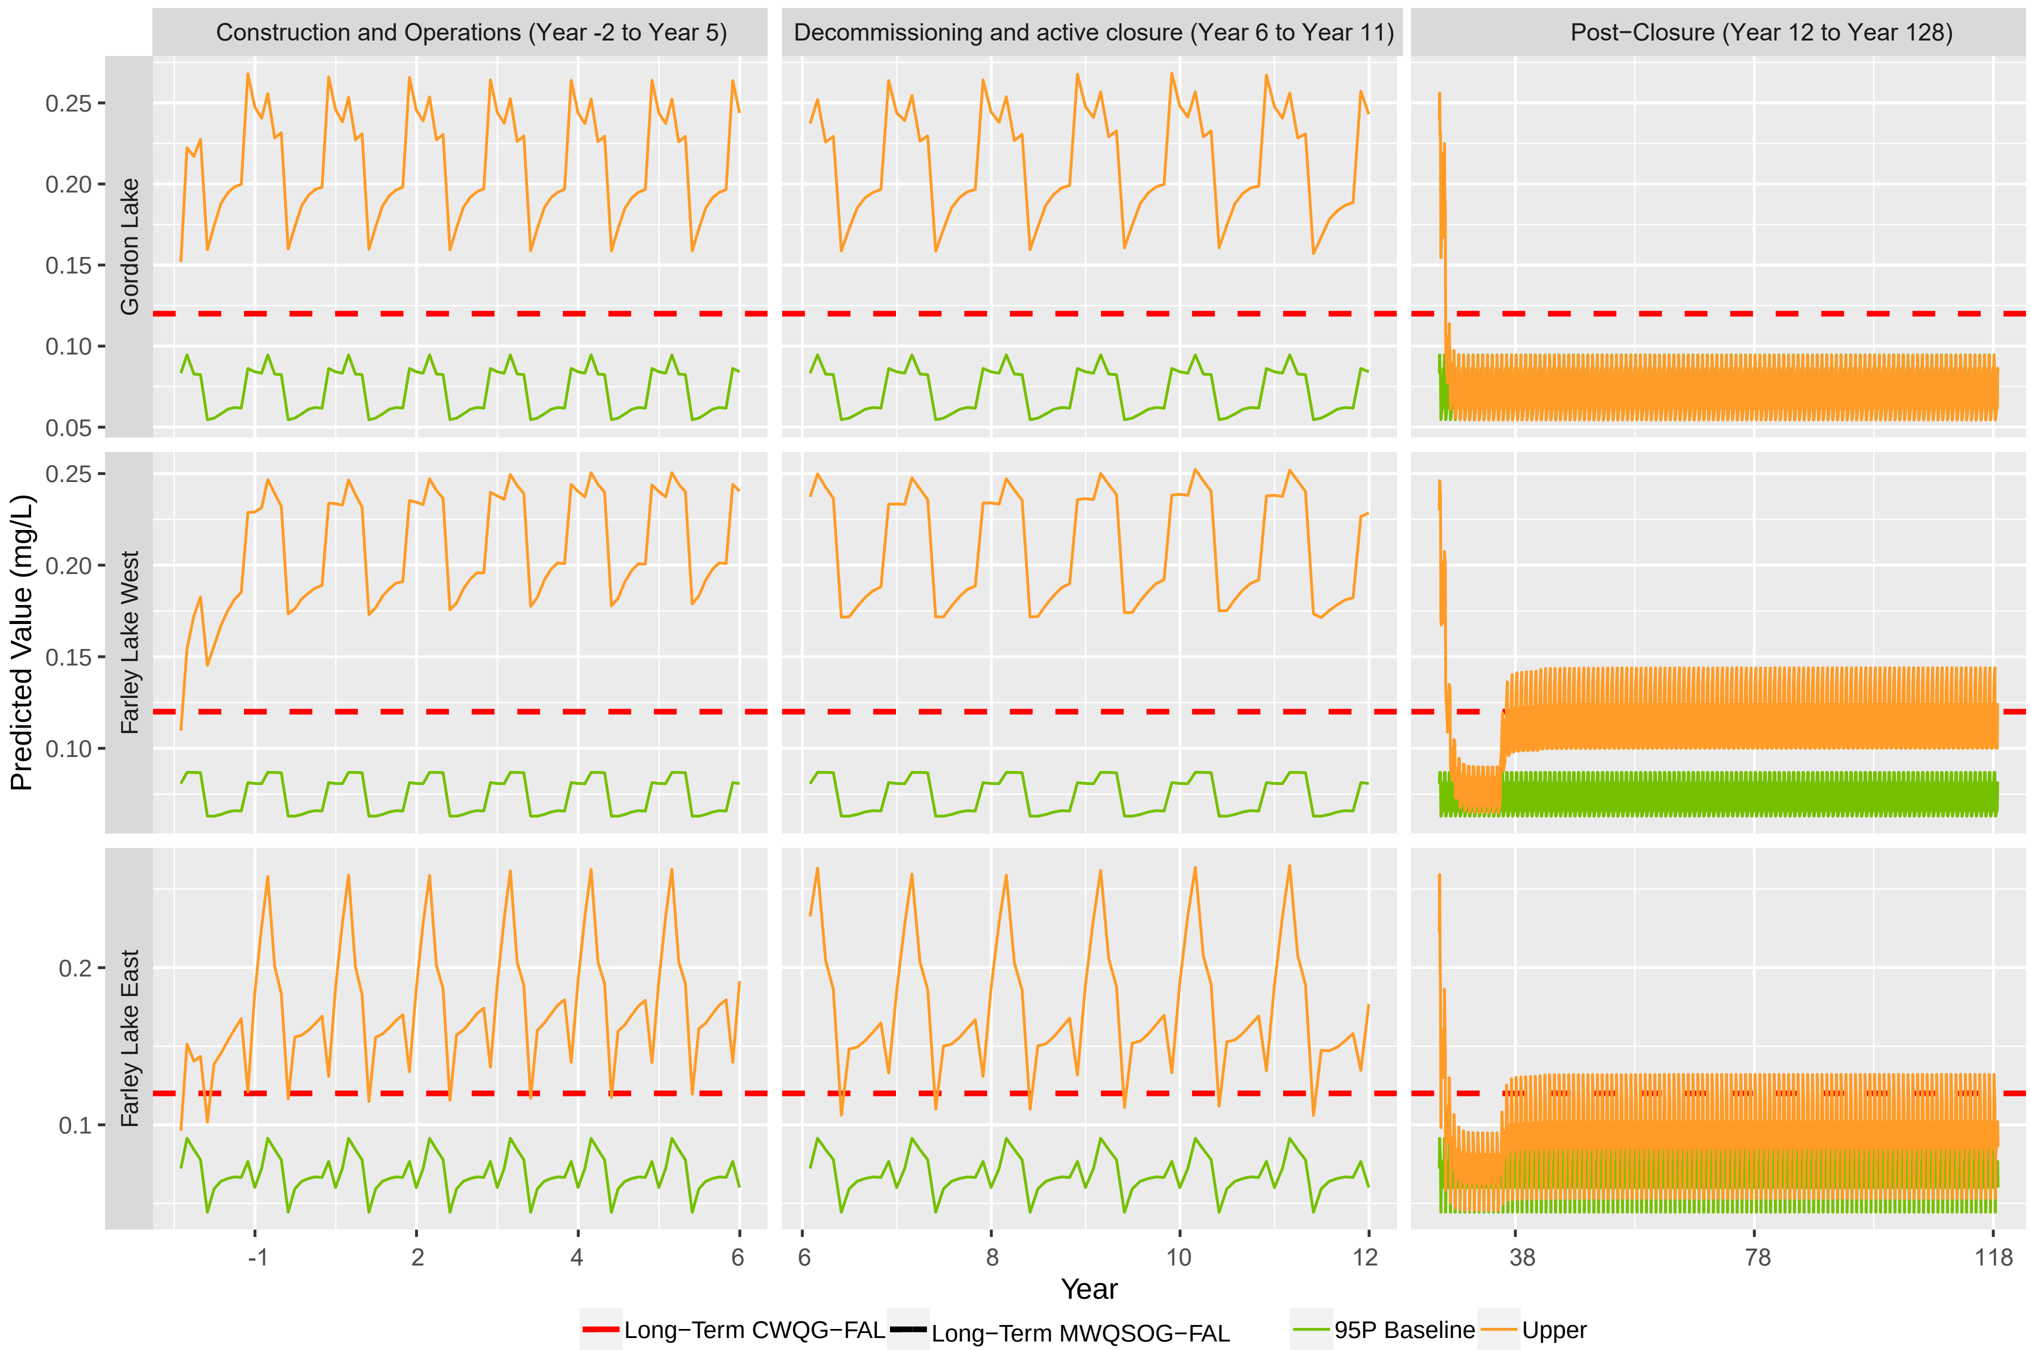
Copper, Total (mg/L)



Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-3: Gordon - Predicted Concentrations in Receivers - Upper Case

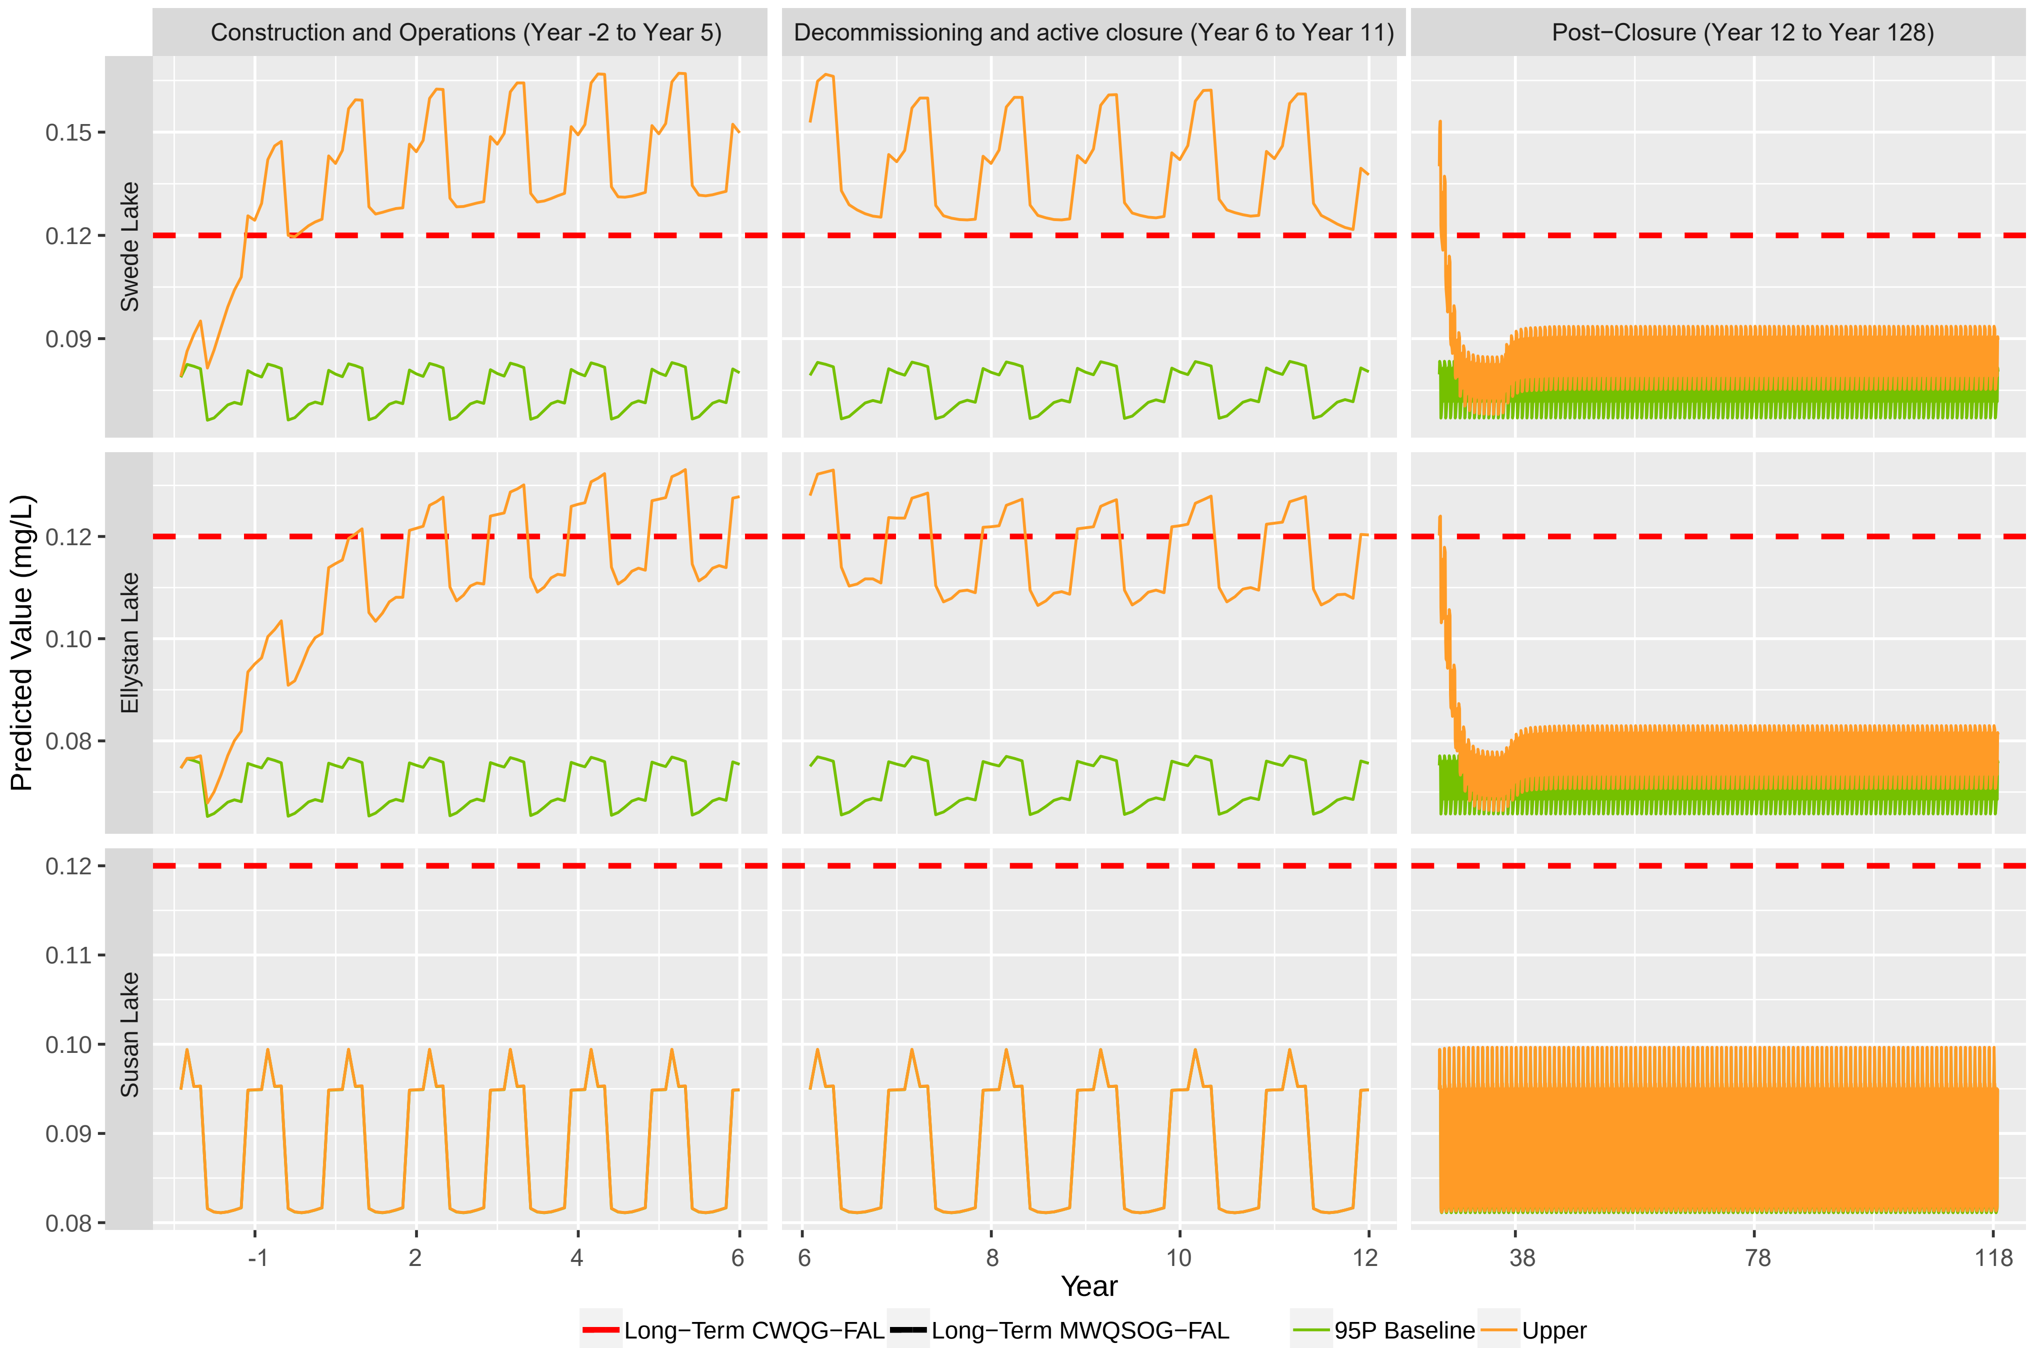
Fluoride, (mg/L)



Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-3: Gordon - Predicted Concentrations in Receivers - Upper Case

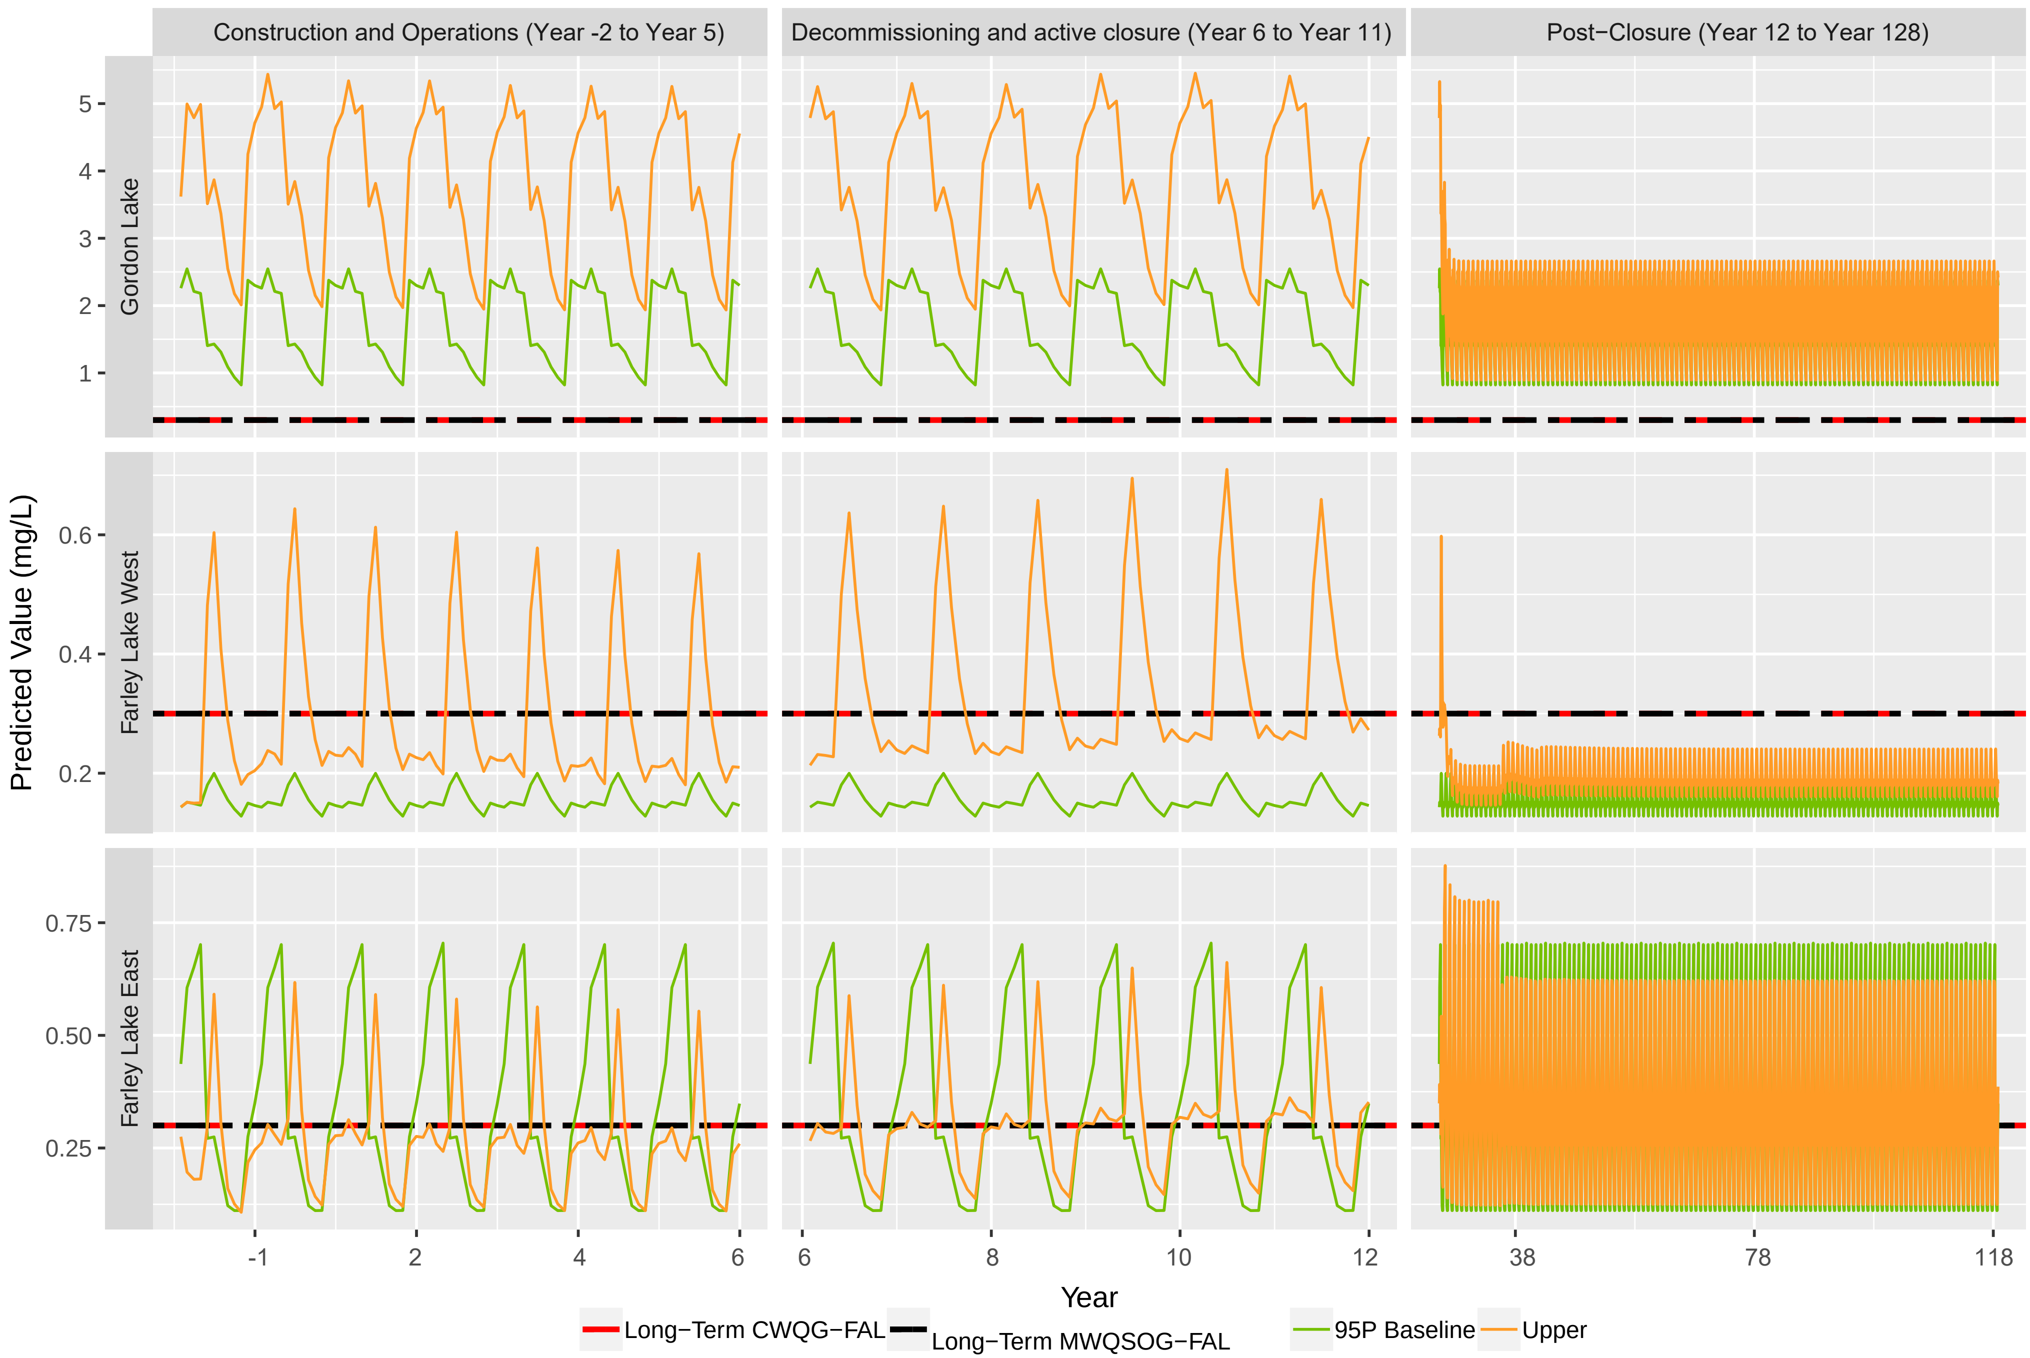
Fluoride, (mg/L)



Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-3: Gordon - Predicted Concentrations in Receivers - Upper Case

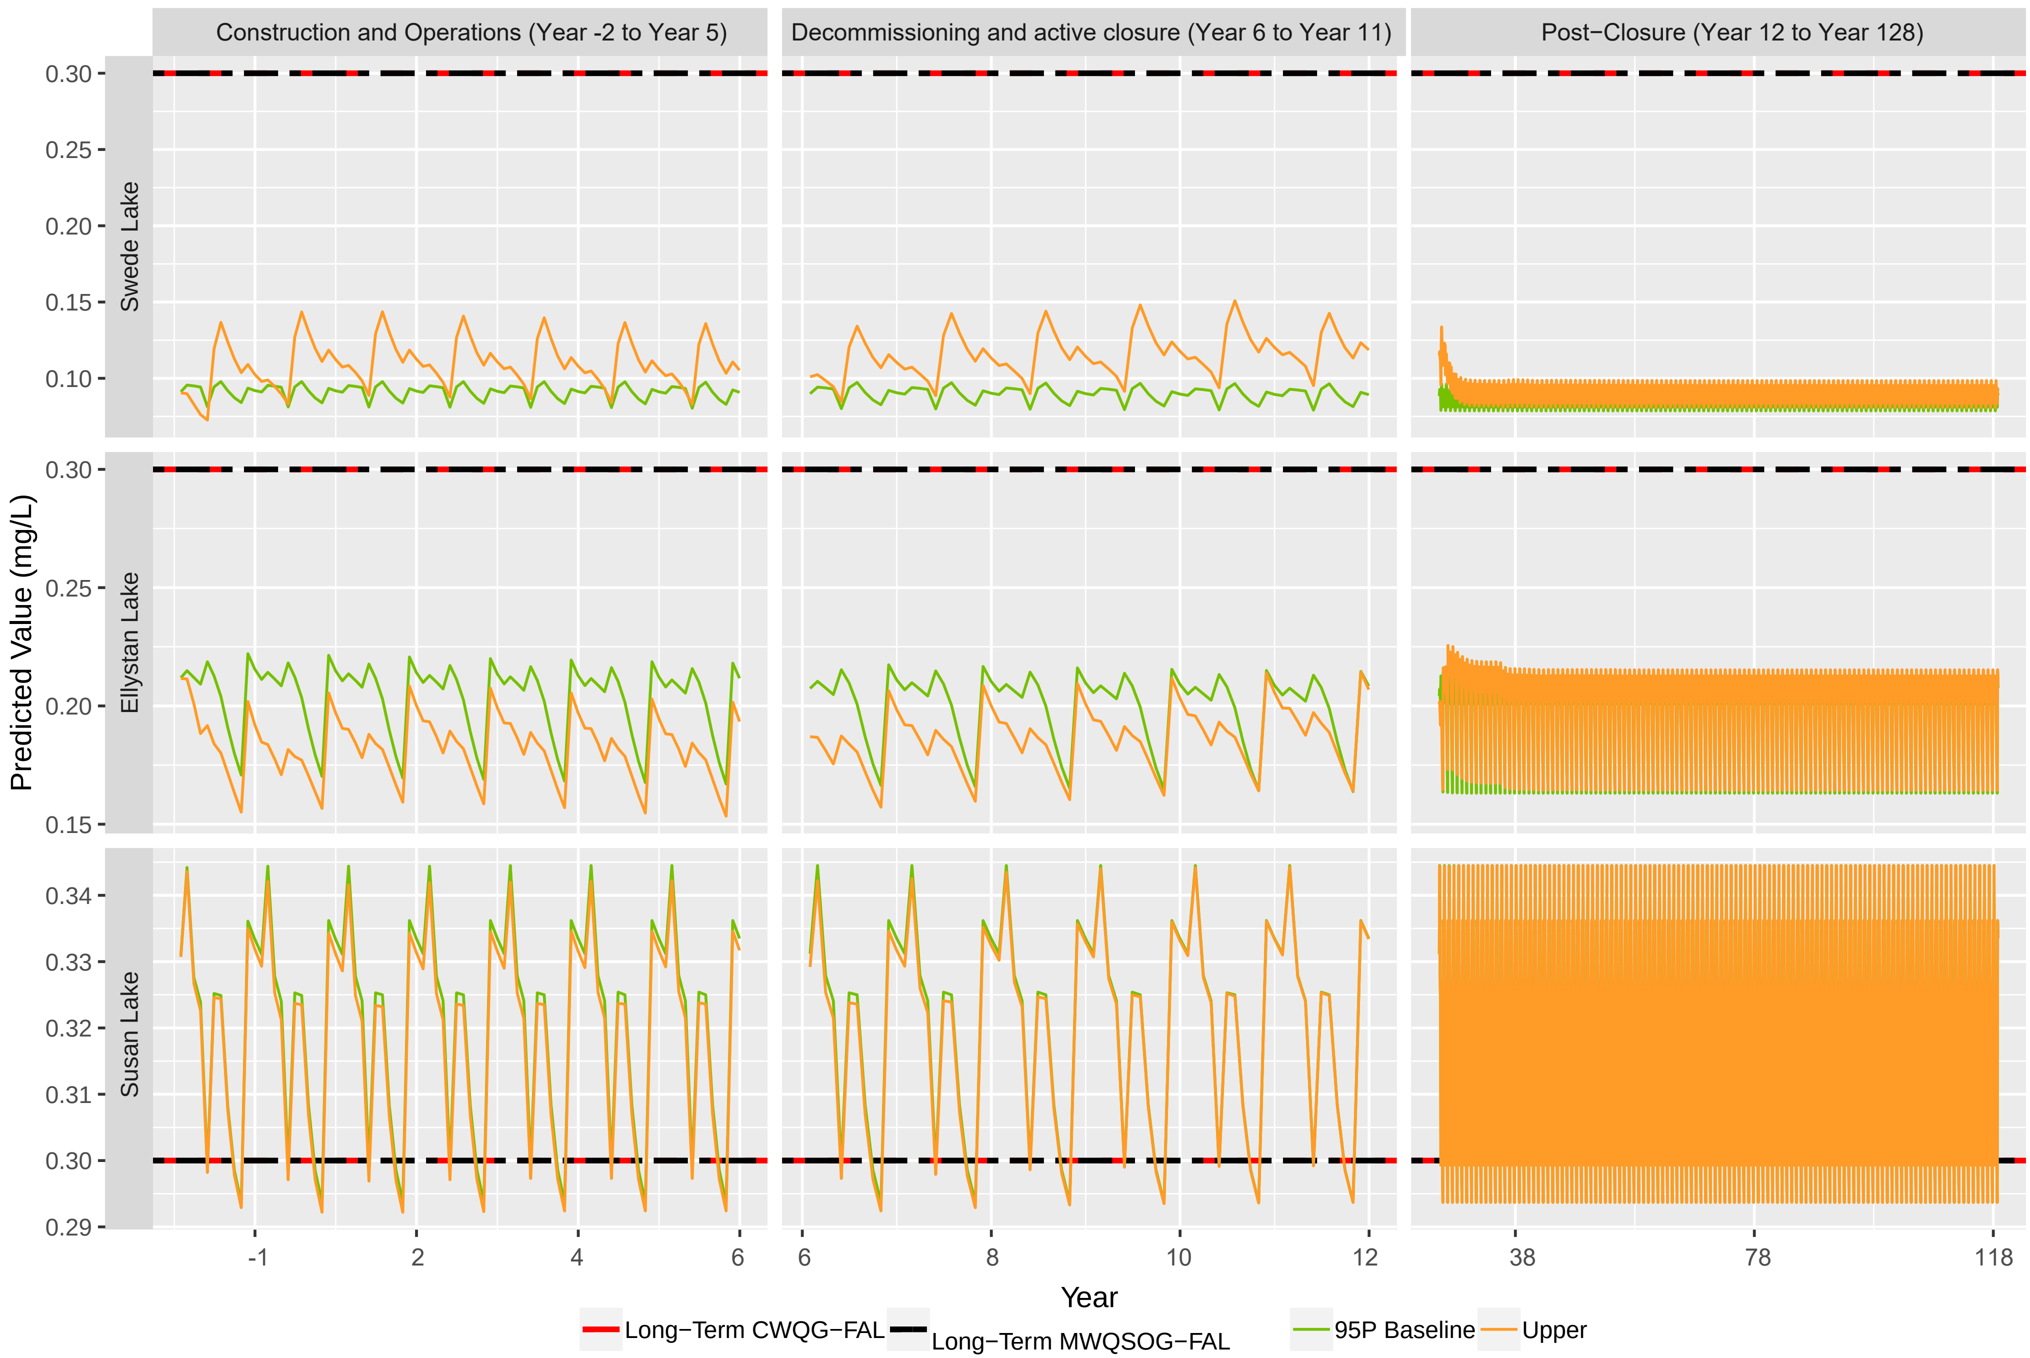
Iron, Total (mg/L)



Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-3: Gordon - Predicted Concentrations in Receivers - Upper Case

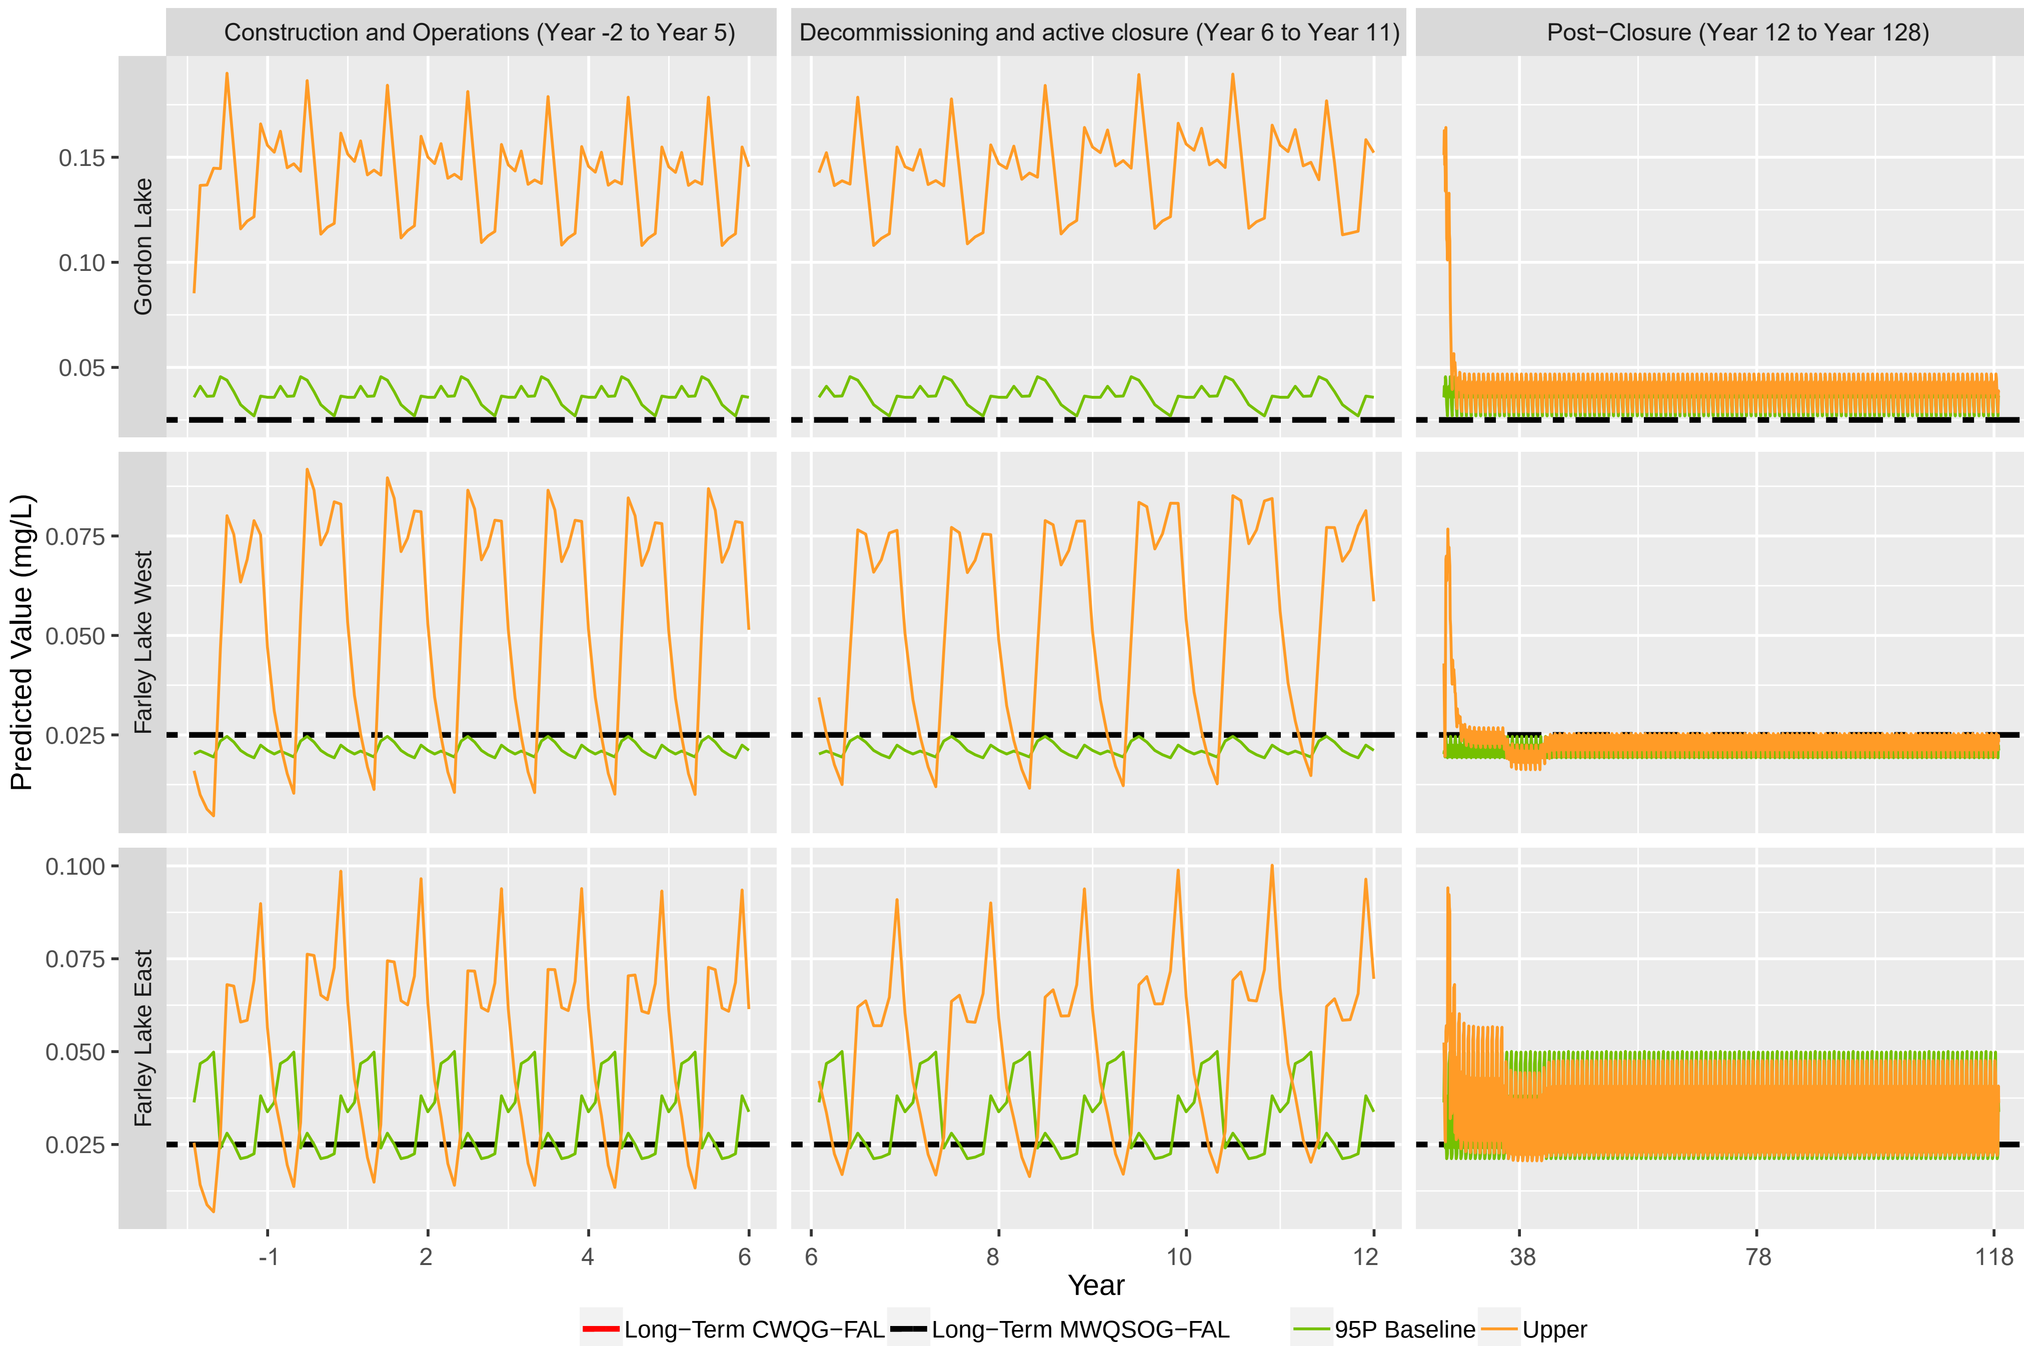
Iron, Total (mg/L)



Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-3: Gordon - Predicted Concentrations in Receivers - Upper Case

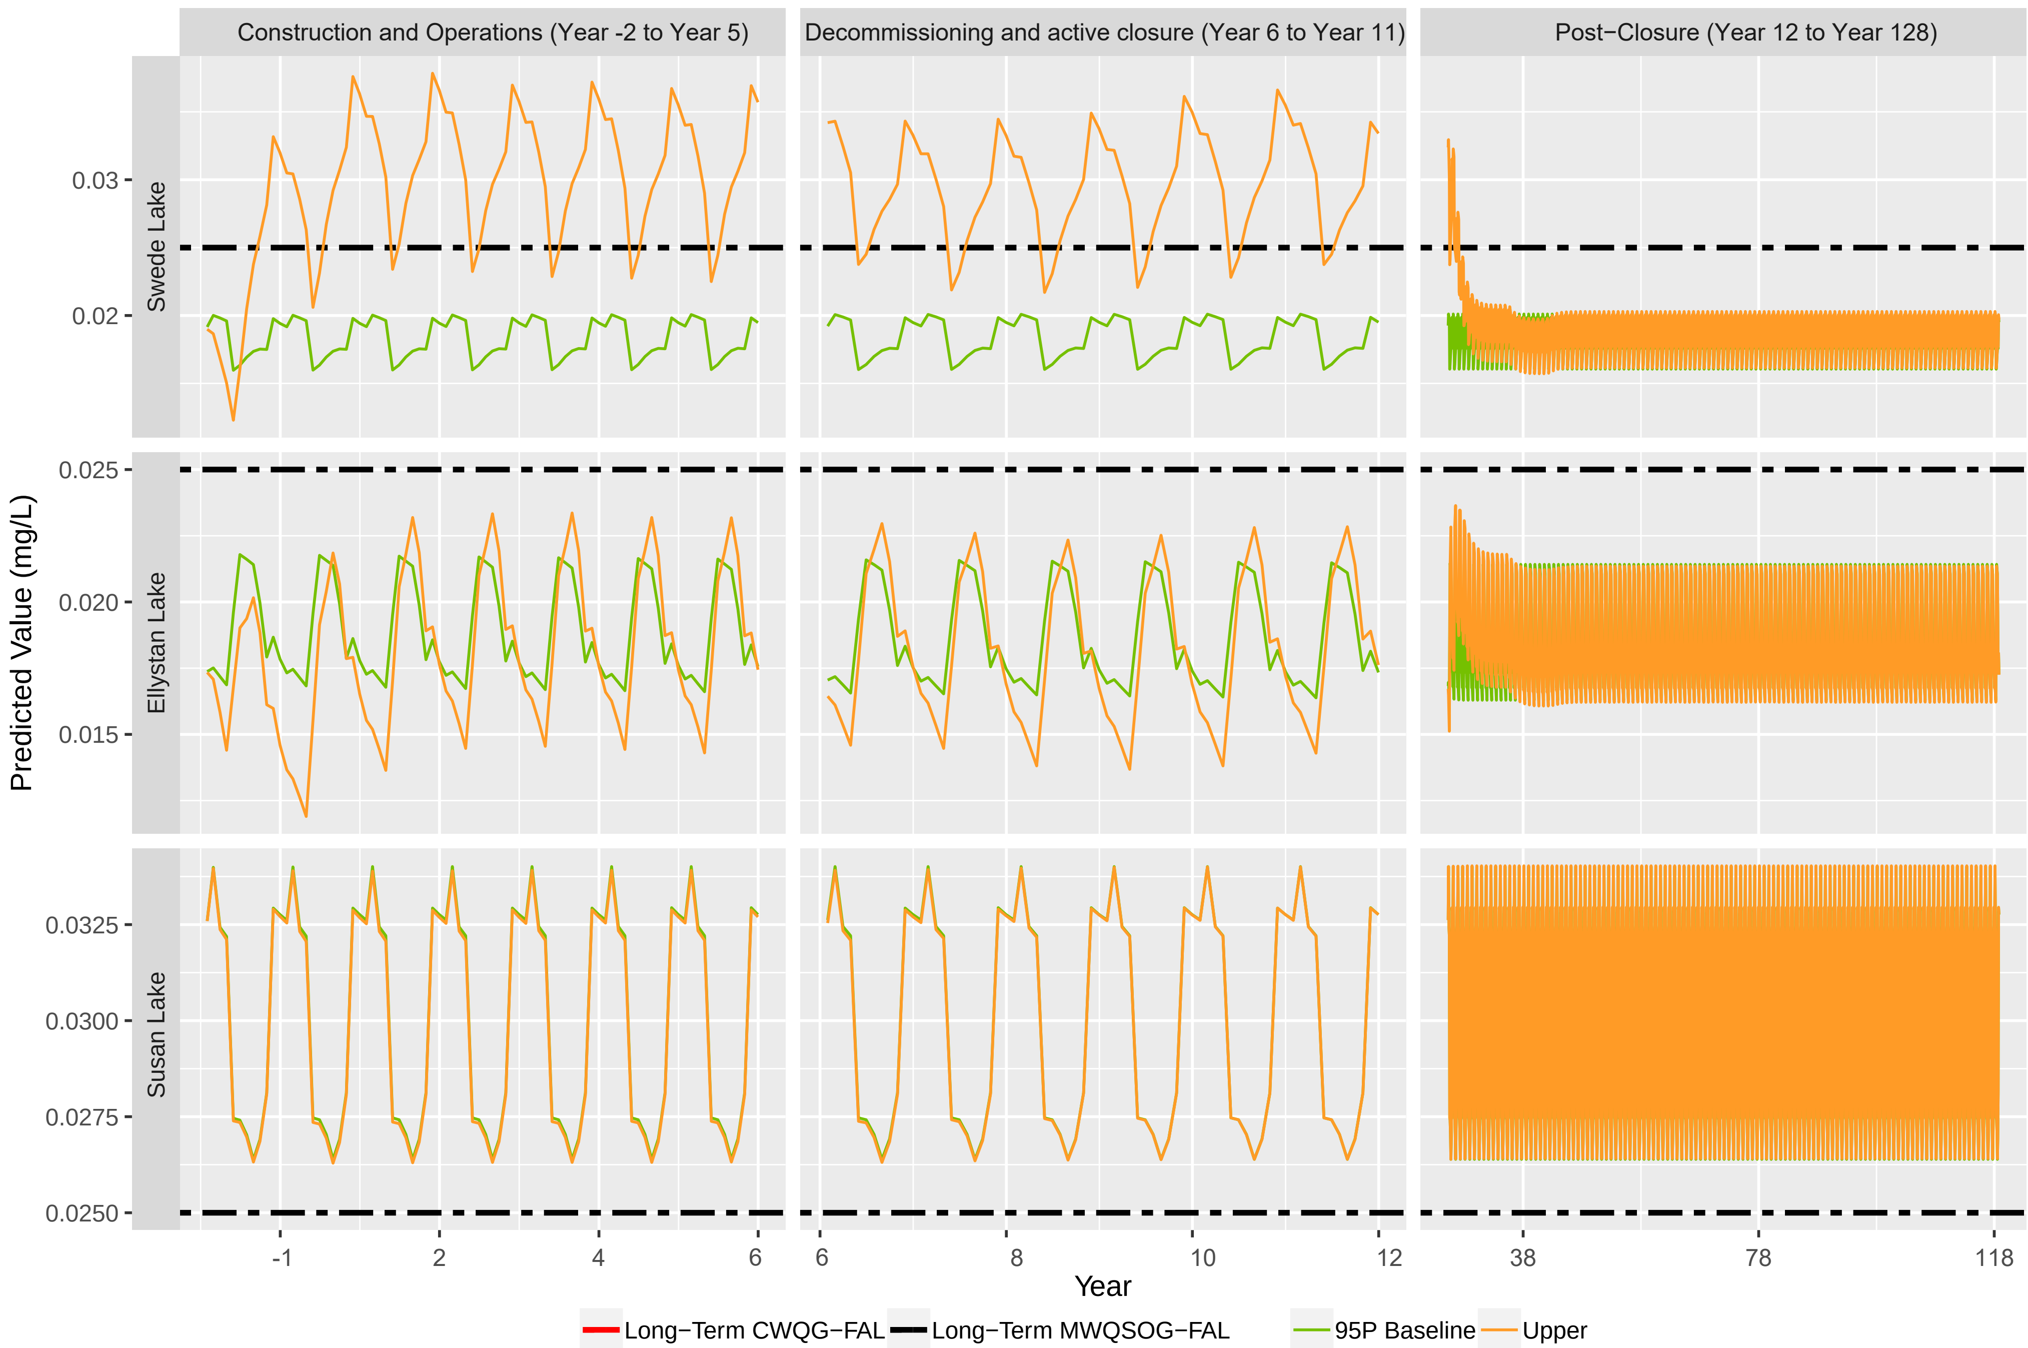
Phosphorus, Total, (mg/L)



Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-3: Gordon - Predicted Concentrations in Receivers - Upper Case

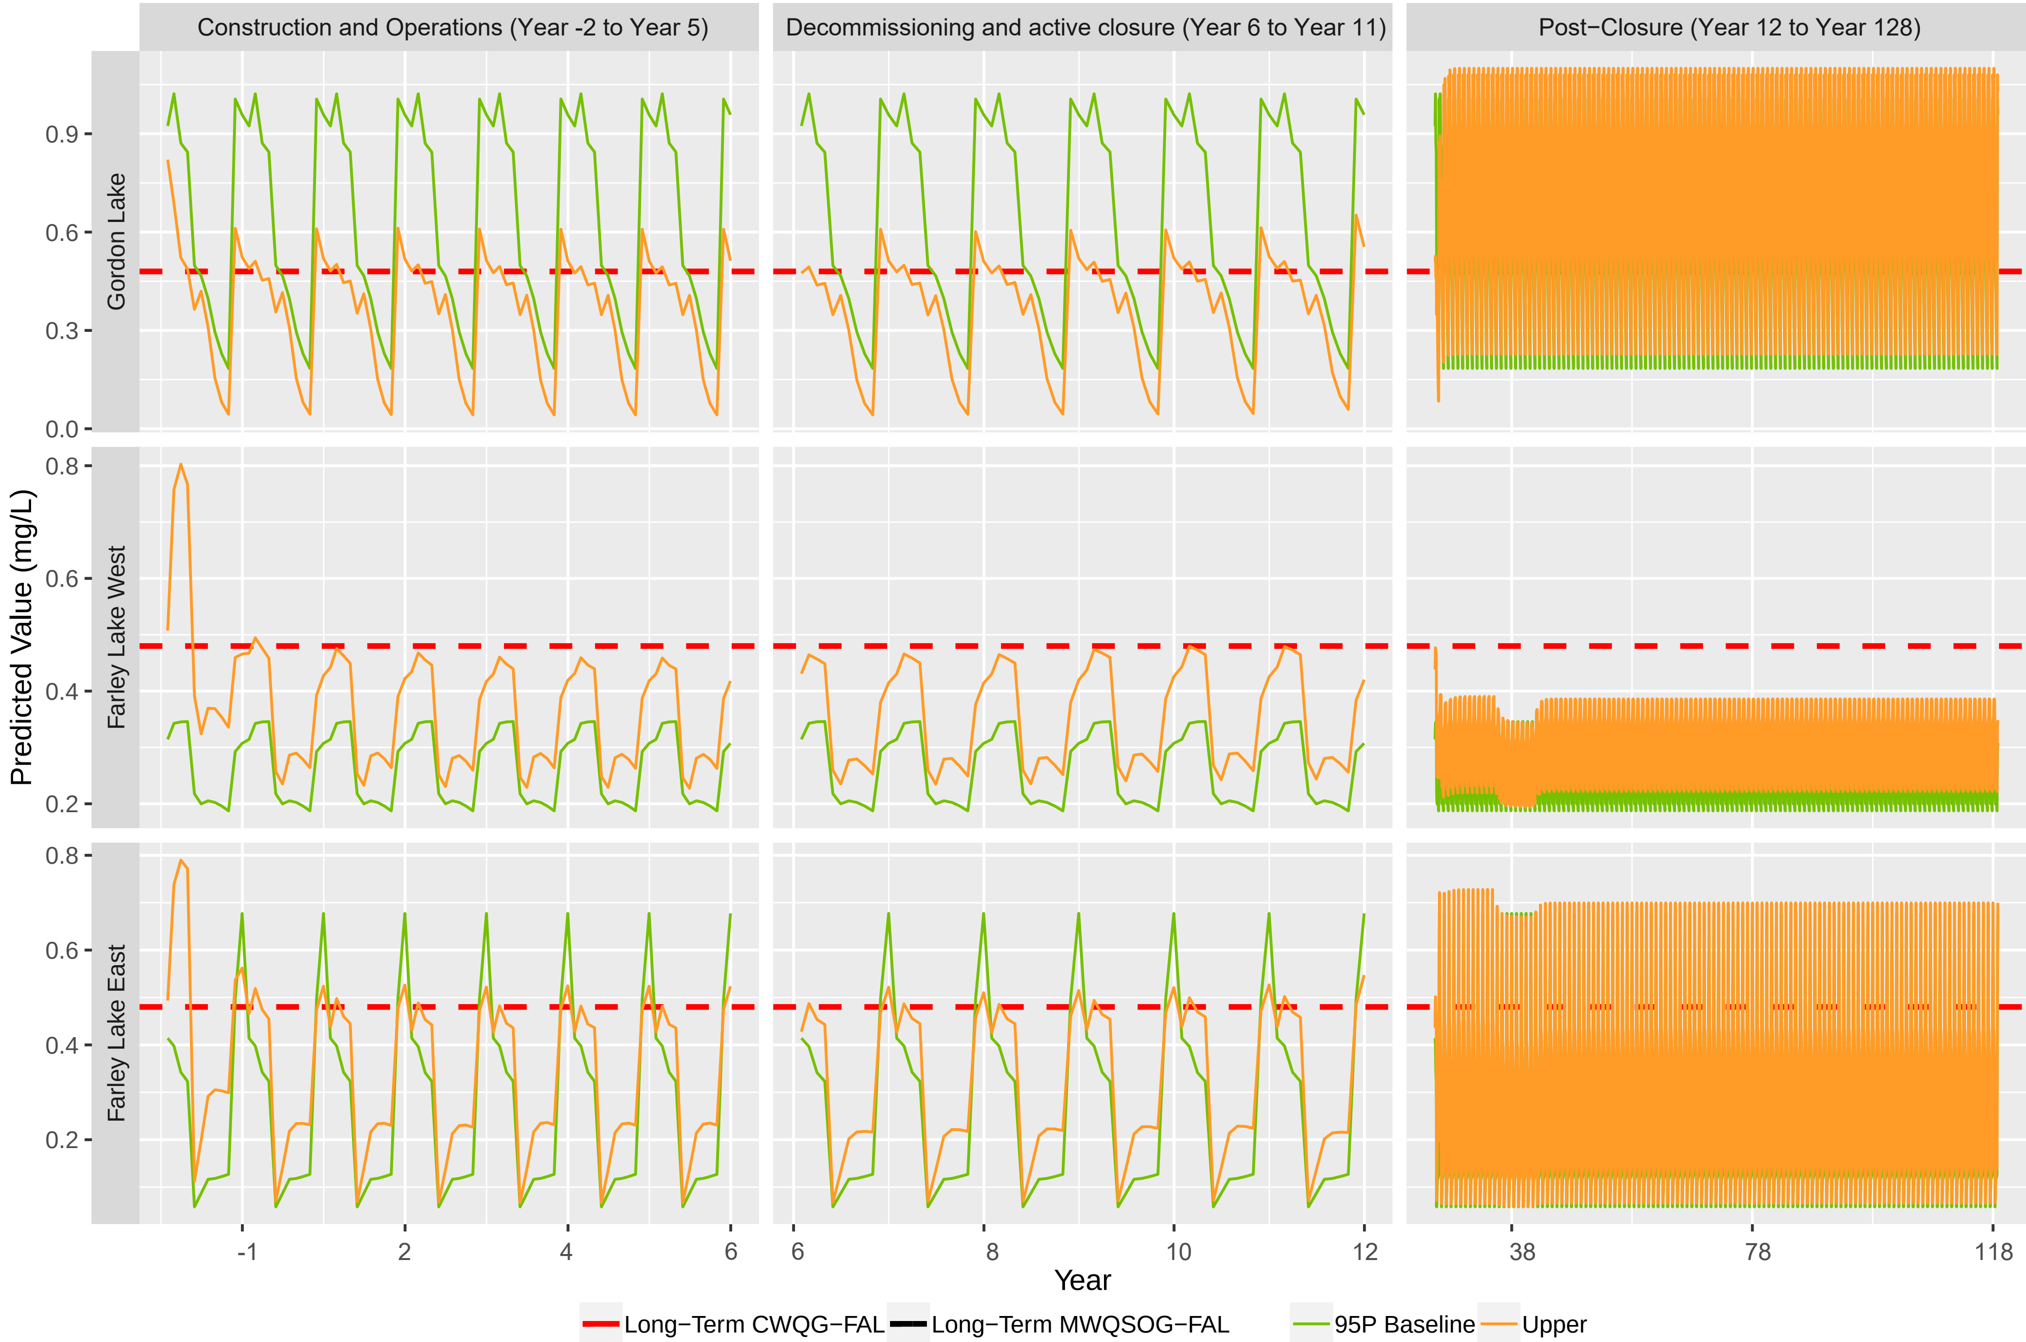
Phosphorus, Total, (mg/L)



Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-3: Gordon - Predicted Concentrations in Receivers - Upper Case

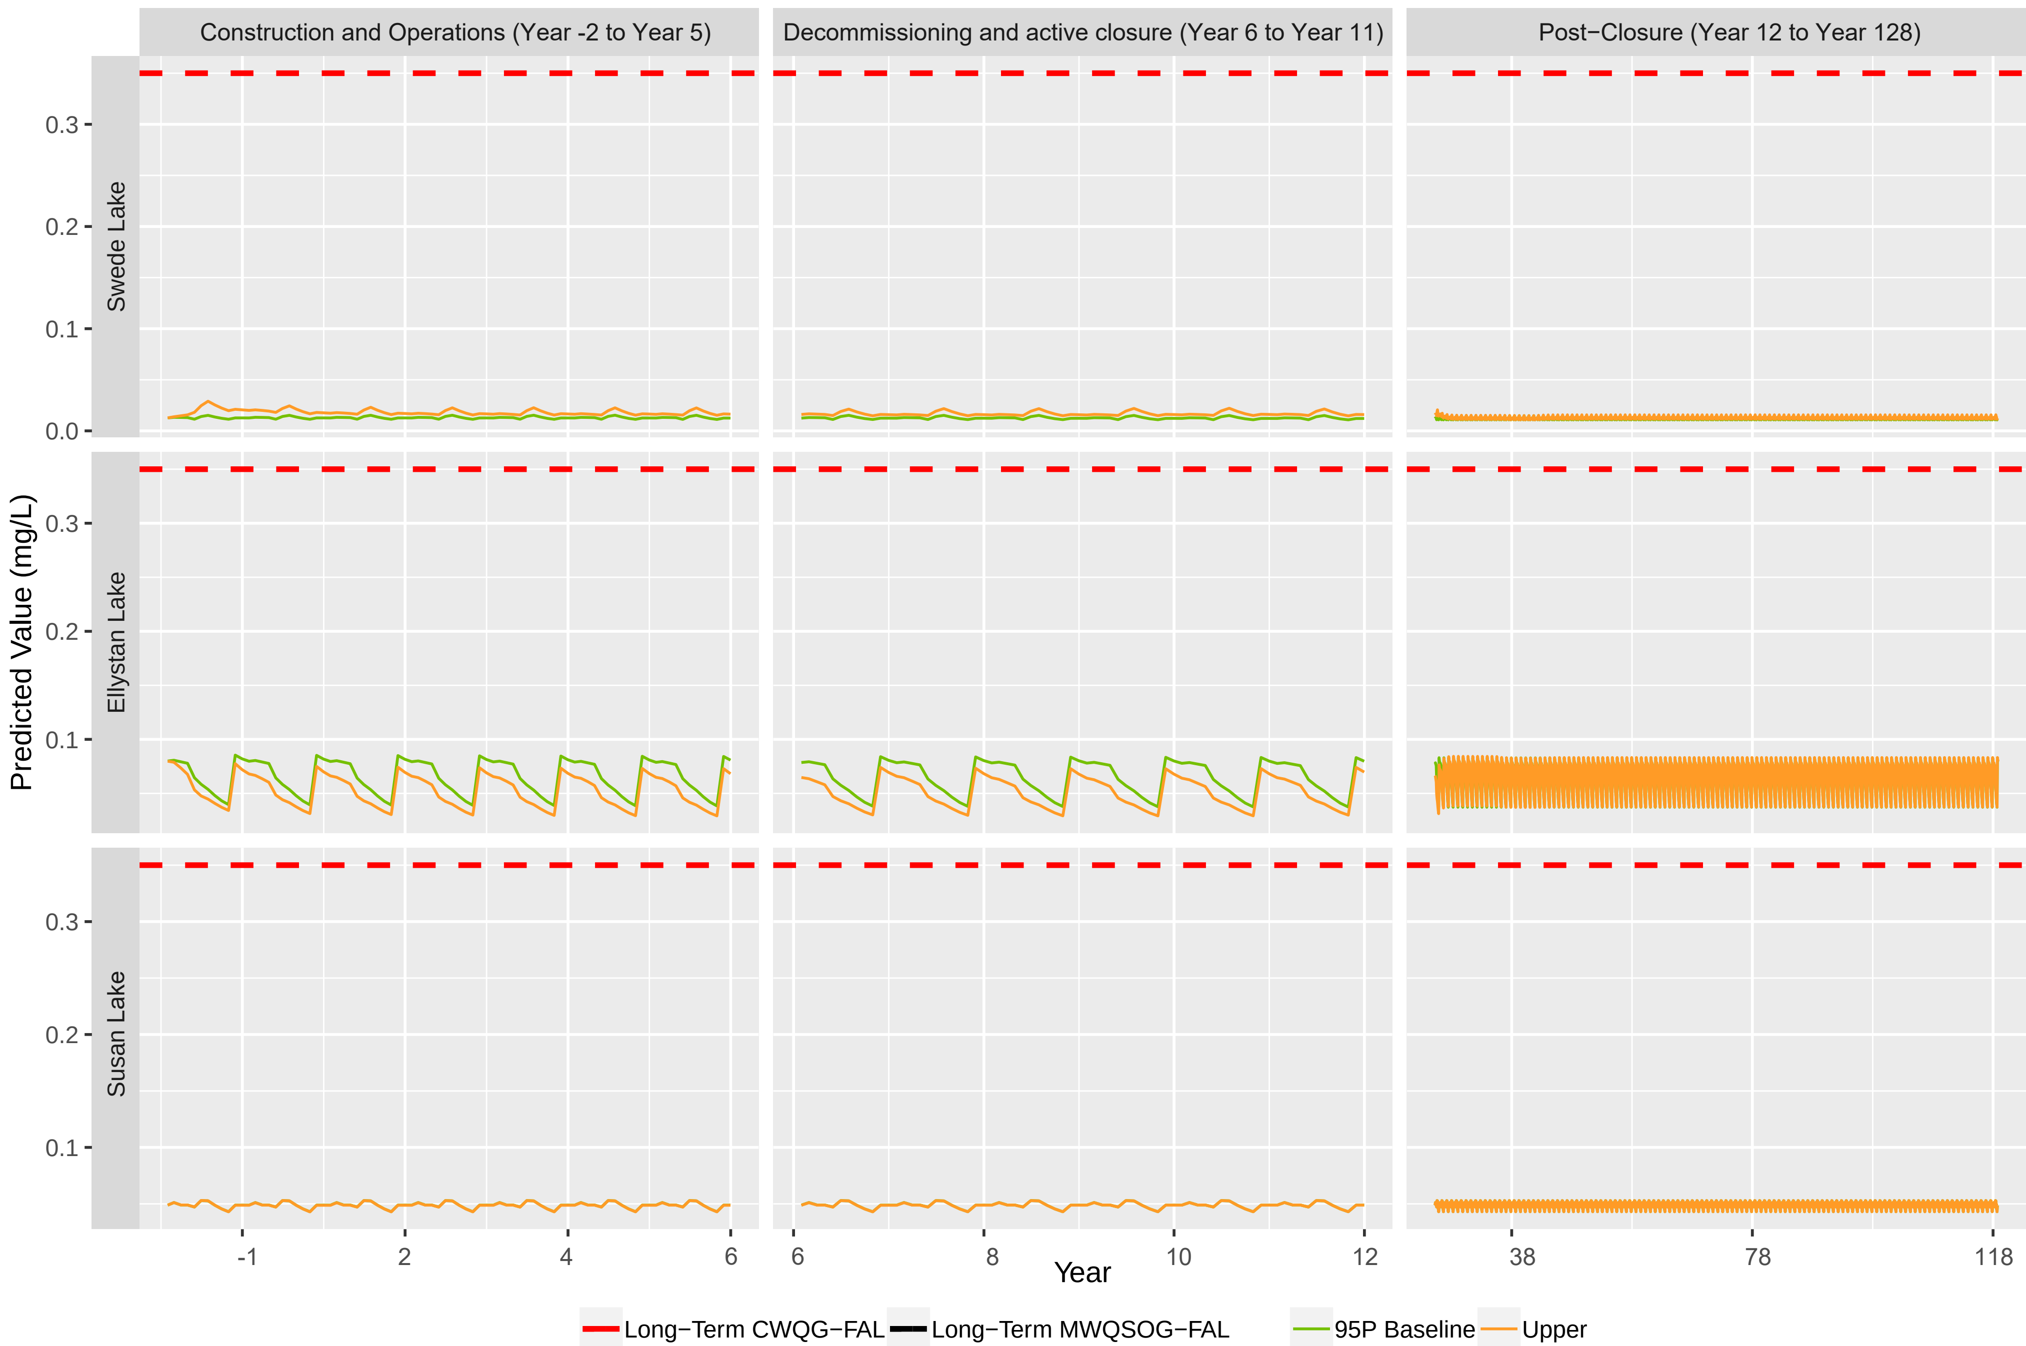
Manganese, Dissolved (mg/L)



Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix I-3: Gordon - Predicted Concentrations in Receivers - Upper Case

Manganese, Dissolved (mg/L)



Upper case: elevated geochemical inputs and 95th percentile or Log 10 of 95th percentile for baseline water quality inputs.
Calculated guidelines are plotted at the median value for the parameter.

Appendix K MEMORANDUM ON MINE ROCK WETTING

Stantec

Memo

To:	LLGP Project Team	From:	Mark Steinepreis Waterloo Office
File:	By Email	Date:	May 7, 2020

Reference: Infiltration of precipitation and wetting time for the proposed Gordon and MacLellan Mine Rock Storage Areas

INTRODUCTION

Mine rock storage areas (MRSAs) are planned at the Gordon and MacLellan mine sites as part of the Lynn Lake Gold Project. The MRSAs are approximately 45 m and 40 m tall at Gordon and MacLellan respectively. Water that infiltrates into the MRSAs can potentially migrate to seepage collection ditches via toe seepage discharge, or to groundwater via basal seepage into the soil underlying the MRSAs. As the infiltrated water passes through the porous stockpile, metal leaching (ML) and acid rock drainage (ARD) processes may occur that could affect the quality of the toe seepage and basal seepage. Therefore, the mine rock wetting process has been evaluated for inclusion in the environmental water balance / water quality model for the Gordon and MacLellan sites.

Mine rock is typically placed dry and has the capacity to store infiltrating precipitation in the pore space. This storage capacity delays the wetting up of the pile. The wetting front that develops within the matrix material (<5 mm fraction) moves deeper into the pile over the years following placement, before breakthrough of matrix flow into the subsurface or seepage through the toe. Steady state flow will occur once the infiltration and the unsaturated hydraulic conductivity profile of the material reach an equilibrium.

This memo presents unsaturated seepage analyses to estimate the wetting time for the proposed MRSAs at the Gordon and MacLellan sites. These analyses include the simulation of flow through the MRSA during operations, and the continued progression of the wetting front into the closure period following the placement of a soil cover that is planned as part of the closure strategy.

MODELLING APPROACH

Flow pathways for precipitation falling on the crest of the MRSAs include evaporation, surface runoff and infiltration. As mine rock typically comprises grain sizes ranging from clay to boulder sizes (Amos et al. 2015), it is generally accepted that water infiltrating into the waste rock pile will follow two main pathways:

- gravity-driven flow through large pore spaces (macropores)
- capillary-driven flow through matrix materials (<5 mm fraction) that are present around and between cobbles and boulders (Smith and Beckie 2003; Nichol et al. 2005)

Figure 1 presents a schematic of the flow pathways for precipitation falling on the pile, and the infiltration within the pile.

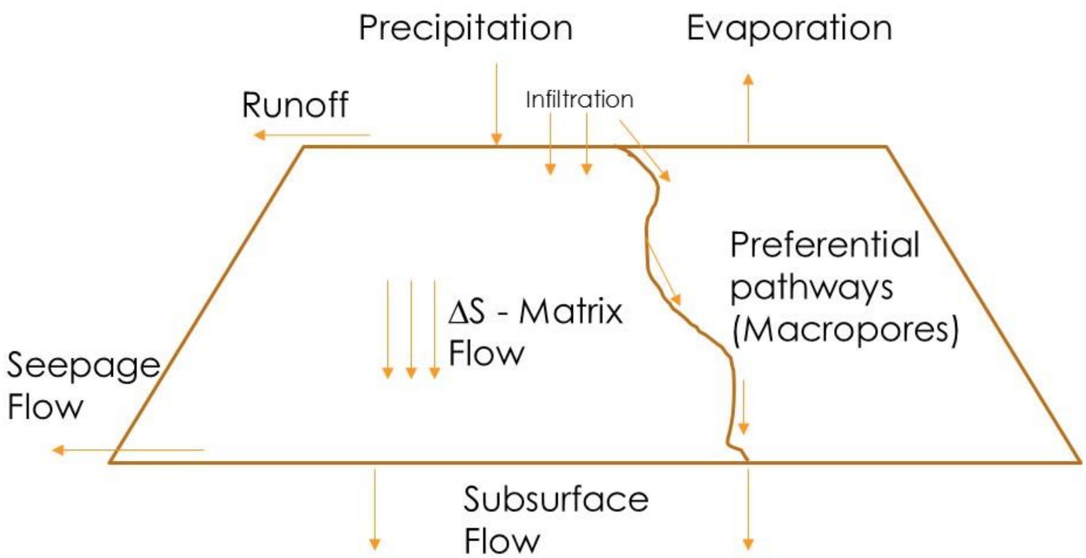

Figure 1 – Water Flow Pathways Around and Within a Mine Rock Pile

The simulations in this memo were conducted using the software code MACRO 5.2 (MACRO) to predict the flow through the MRSAs. MACRO is a 1-dimensional, dual-permeability model for water flow in porous media. The model separates flow through the micropores and macropores and is well suited for the mine rock context, as demonstrated by Keller et al. (2015).

Although mine rock is placed in lifts which has the potential to hasten the passage of the wetting front into the pile, MACRO is only able to simulate a single lift. A previous study (Steinepreis, 2018) considered the effect of multiple lifts in the software SEEP/W®, which is a single-permeability model and therefore cannot consider separate macropore and micropore flow. Informal analyses were carried out in SEEP/W®, and the difference in wetting time from a single lift and multiple lifts was relatively minor. Therefore, the results from MACRO are assumed to be suitable for evaluation of downstream effects.

The MACRO model inputs are discussed in the following subsections. The pertinent model outputs from the MACRO analyses were the flows through the micropores and macropores with time, for incorporation into the mine wide water balance. The wetting process is assessed through the moisture content profile of the material with depth and time.

MACRO MODEL INPUTS

Climate

An estimation of evaporation, runoff and infiltration was required. In lieu of a numerical evaporation model, it was assumed for the uncovered pile that 50% of the annual average precipitation is lost to evaporation and there is no runoff, i.e. the remaining 50% of annual precipitation will percolate into the pile. The 50% net infiltration assumption is similar and slightly more conservative than Smith and Beckie (2003), who observed a net annual infiltration of 55% for a constructed pile experiment in northern Saskatchewan. The assumed annual evaporation was split into a monthly breakdown based on a Thornthwaite analysis (Thornthwaite, 1948) using the United States Geological Survey graphical user interface.

The annual evaporation was increased to 55% of annual average precipitation for the covered pile, and runoff coefficients were estimated.

Precipitation data was obtained from Environment Canada, Lynn Lake Station A (Station ID 5061646, Years 1969-2005). The MACRO model considers daily input precipitation.

Material Properties - Mine Rock

MACRO models the flow through unsaturated porous media using the soil water content curve (SWCC) for each material type. A literature search was carried out to obtain the properties of mine rock for similar operations in lieu of site-specific data for the Gordon and MacLellan sites. The University of Waterloo in Ontario has carried out numerous studies on the hydrogeologic properties of the mine rock piles at the Detour Gold Mine. SWCCs were developed for the matrix (<4.75 mm) fraction of mine rock samples from a historical pile at Detour (Cash 2013). These SWCCs have been assumed to be applicable to the matrix of the mine material for this project.

Cash (2013) presented several SWCC curves for matrix samples, and the mean curve from the upper porosity range (>0.3) was selected for simulation. The MACRO model requires the Van Genuchten (1980) parameters as inputs, which were obtained by trial and error using SEEP/W®. The same software was used to calculate the unsaturated hydraulic conductivity curve from the input SWCC. The partition between micropore and macropore flow was set at 0.2 m^3/m^3, per the Keller et. al. (2015) study. The corresponding matric suction from the SWCC curves was 20 kPa, which is higher (i.e. wetter) than the corresponding matric suction (10 cm or approximately 1 kPa) in the Keller study. Flow will be through micropores when the moisture content of the material is less than 0.2 m^3/m^3, and macropore flow will be triggered when the moisture content is higher. Preferential micropore flow at lower moisture contents has been recognized as counterintuitive (Swanson, 1999).

Figure 2 presents the mean SWCC curves and the calculated unsaturated hydraulic curve that was input for the mine rock in the simulations, and Table 1 presents the Van Genuchten parameters. The shaded areas of the curves are essentially not used, as macropore flow is triggered in this range which is assumed to travel rapidly to the base of the pile.

Reference: **Infiltration of precipitation and wetting time for the proposed Gordon and MacLellan Mine Rock Storage Areas**

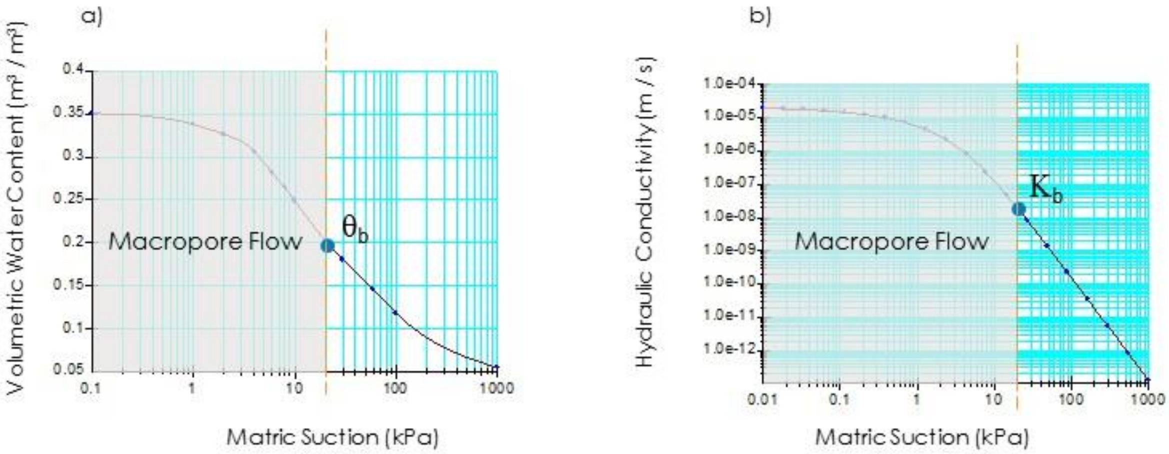

Figure 2 - a) Soil Water Content Curve (Cash 2013) and b) unsaturated hydraulic conductivity curve used for the simulated mine rock pile

Table 1 - Van Genuchten Parameters

Material	N (-)	α (cm^{-1})	K_{sat} m/s	K_b m/s	θ_b m^3/m^3	θ_{res} m^3/m^3
Waste Rock	1.5	0.014	$2x10^{-4}$	$2x10^{-8}$	0.2	0.03

Note: K_{sat} was set to ensure that flow through the macropore will essentially be instantaneous, and was assumed to be an order of magnitude above the saturated hydraulic conductivity of the matrix material (Figure 2b)

Mine rock is typically placed dry, i.e., the volumetric water content is below 0.06 m^3 / m^3 (Mine Environment Neutral Drainage,1995), and the initial water content was assigned accordingly. The flow boundary condition on the crest of the geometry was the infiltration from each precipitation event (i.e. precipitation subtract evaporation and runoff). The flow boundary condition at the base of the geometry was the unit hydraulic gradient, essentially simulating free drainage.

Material Properties - Cover Material

The mean average annual evaporation for the covered pile was assumed to be 55%, i.e. nominally higher than the bare waste rock. Runoff was assumed to occur, and to estimate the percentage of the excess water that runs off and infiltrates the infiltration factors from the Ontario Ministry of Environment and Energy (now the Ontario Ministry of Environment, Conservation and Parks) were used. An infiltration factor of 0.4 was used for open sandy loam (MOEE, 1995), i.e. 40% of the excess water was assumed to infiltrate the cover which is equal to 19% of the annual average precipitation.

The available material on site to use as cover is typically sandy with variable fines. Table 2 presents the Van Genuchten parameters for the cover material, which were obtained from a sample function of silty sand from SEEP/W®, typical of the overburden materials that will be available to use as a cover.

Table 2 - Van Genuchten Parameters

Material	N (-)	α (cm^{-1})	K_{sat} m/s	K_b m/s	θ_b m^3/m^3	θ_{res} m^3/m^3
Cover	1.85	0.02	$2x10^{-4}$	$6.5x10^{-6}$	0.295	0.01

SIMULATIONS – OPERATIONS AND CLOSURE

The MACRO model considered operations and closure. The operating mine lives of the Gordon and MacLellan sites are 5 years and 13 years respectively, after 3 years of pre-production with minimal waste rock production. Active Closure is assumed to take 6 years after completion of operations, during which a cover (0.5 m thick) will be constructed using available site materials. The time period after Active Closure is referred to as Post-Closure. For the purpose of the analysis the conservative assumption was that the cover was not in place during Active Closure, and placed instantly at the commencement of Post-Closure.

The proposed mine development schedule for the two sites is presented on Table 1.

RESULTS

WETTING FRONT AND TIMES FOR OPERATIONS/ACTIVE CLOSURE

Figure 3 presents the progression of the wetting front through the uncovered mine rock pile from the MACRO analysis. One model adequately describes the Gordon and MacLellan MRSAs, the only difference is the running time (mine years). The wetting front had progressed approximately 25 m by year 12, which is the assumed date of completion of the cover at Gordon. The progression by the end of cover construction at MacLellan was approximately 37 m for the MacLellan pile, near the base of the 40 m pile. The moisture content profile at these times becomes the initial condition for the Post-Closure model.

The equilibrium moisture content is approximately 0.18 m^3/m^3.

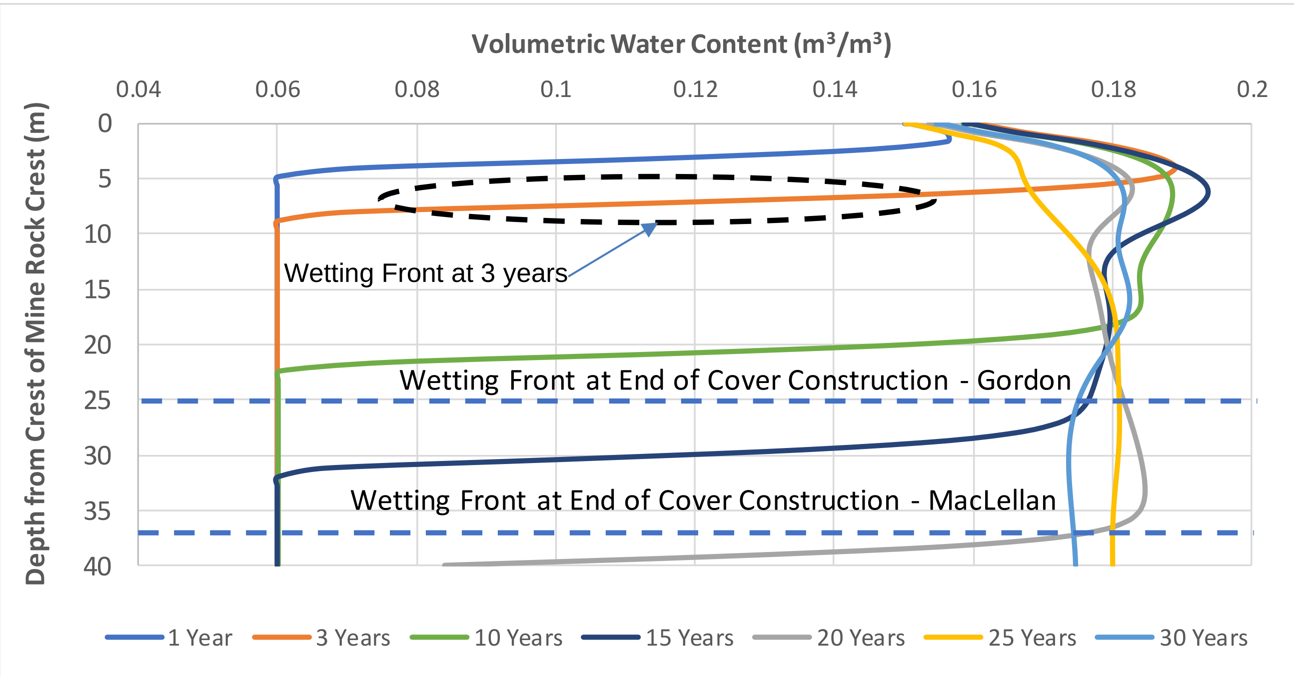

Figure 3 - Progression of the wetting front through the uncovered mine rock pile

Figure 4 presents the flow diagram for the uncovered pile. Macropore flow accounts for approximately 4.3% of the annual average precipitation and micropore flow accounts for the remaining 45.6% (sum total 50% per the assumption made for net annual infiltration).

Flows were calculated for the main body of the pile and the slopes. Considering only the main body would have led to the unreasonable assumption that there would be no runoff or seepage water associated with the mine rock piles until wet up was complete.

The flows for the slopes were similar to the main body, except that runoff was assumed to occur and macropore/micropore flow were both assumed to be instantaneous.

Reference: **Infiltration of precipitation and wetting time for the proposed Gordon and MacLellan Mine Rock Storage Areas**

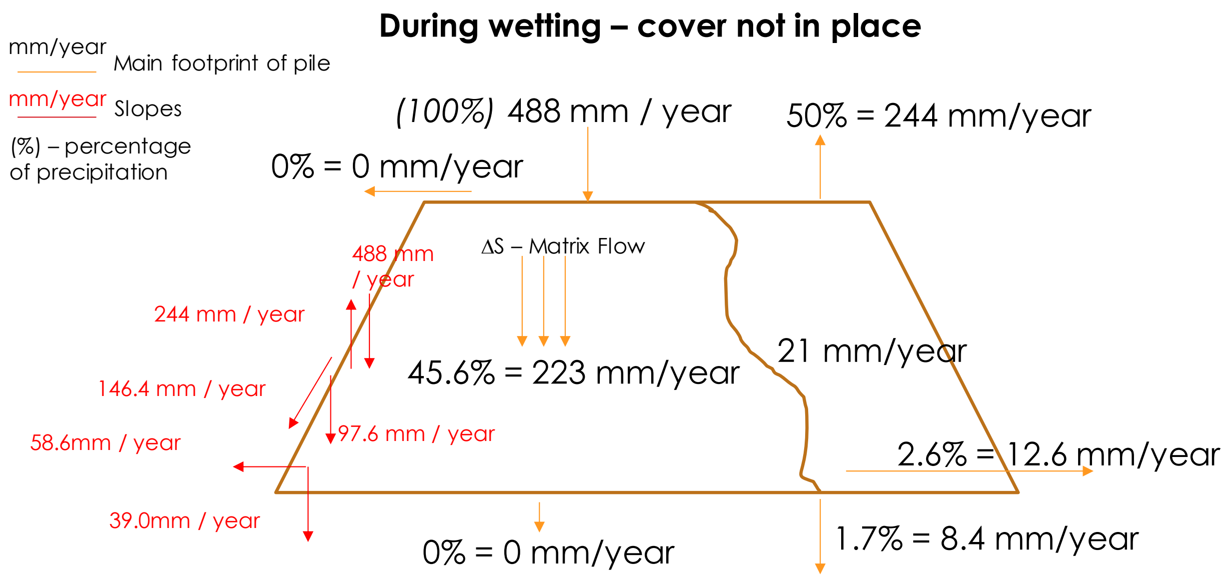

Figure 4 – Water Balance for the MacLellan and Gordon Mine Rock Piles: During the Matrix Wetting and before the Cover Construction is Complete

WETTING FRONT AND TIMES FOR POST-CLOSURE

The wetting up process continued after placement of the cover, and was complete after an additional 19 years at Gordon and 3 years at MacLellan. Figure 5a/b presents the progression of the wetting front through the covered pile. Separate models are required for the Gordon and MacLellan sites due to the different initial condition (Figure 3).

Reference: **Infiltration of precipitation and wetting time for the proposed Gordon and MacLellan Mine Rock Storage Areas**

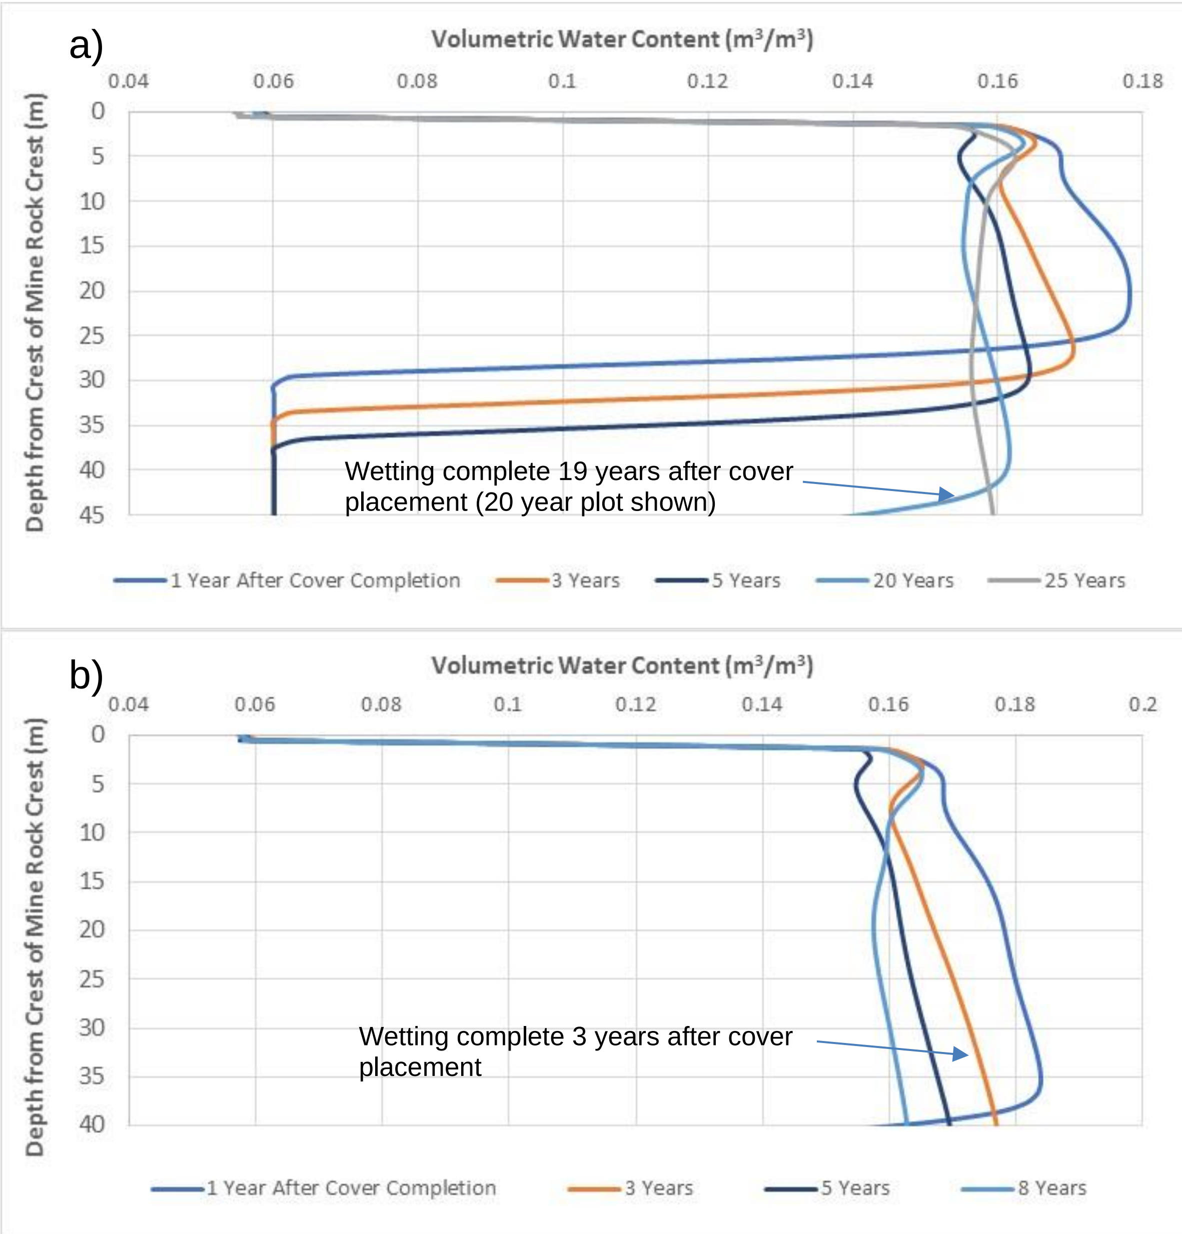

Figure 5 - Progression of the wetting front after placement of the cover on the a) Gordon and b) MacLellan MRSAs

Figure 6 presents the flow diagram for the time period that the cover is in place but before wetting is complete and Figure 7 presents the flows when the piles are completely wet. The flows at the base of the pile were assumed to partially flow into the subsurface and partially seep through the sides of the pile. The MECP infiltration factors were used in this calculation similar to the infiltration at the top of the pile.

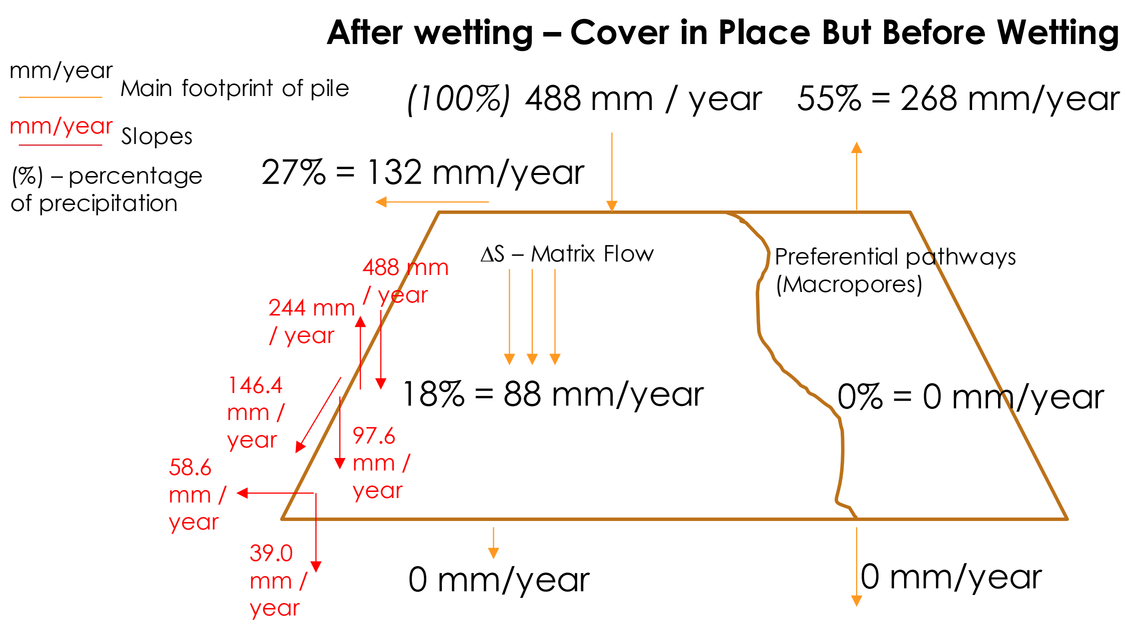

Figure 6 - Water Balance for the MacLellan and Gordon Mine Rock Piles: During the Matrix Wetting and after the Cover Construction is Complete

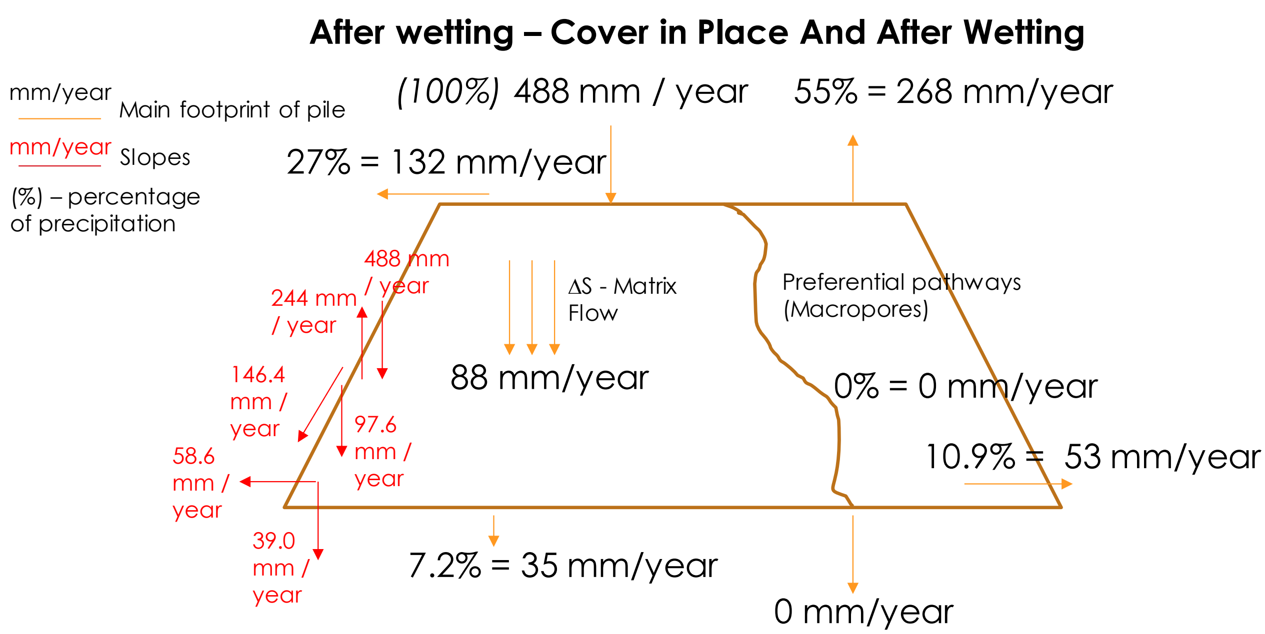

Figure 7 - Water Balance for the MacLellan and Gordon Mine Rock Piles: After the Matrix has Wetted.

LIMITATIONS

Little research has been published on waste rock wetting, and the analyses carried out herewith are considered to be approximate. However, even as the development of this theory continues, it is considered important to recognize that the impacts to water quality from mine rock contact percolation may not be realized until years or decades after placement of the pile.

Field data for climate and hydrogeological properties of the waste rock may be collected during operations to refine the analyses, and is recommended that this be done for to include waste rock wetting in the operational site wide water balance. Following are some limitations on the analyses that may be reconciled with data collection during operations:

- Evaporation on the pile was modelled using assumptions. A Thornthwaite analysis was attempted; however, it is judged that the results were not conservative.
- The hydrogeological characteristics of waste rock are generally not well understood in industry, and design curves for soil moisture content and unsaturated hydraulic conductivity have been developed from a different site and may not apply at the Gordon and MacLellan sites. Particle size distribution tests should be carried out on the matrix (<5mm fraction) material during operations and compared with the results Detour to consider the applicability of the data from the latter to the Gordon and MacLellan sites.
- The analyses have not been calibrated against field measurements. This is not possible at the pre-feasibility stage of the project. V-notch weirs or similar may be placed at toe seeps during operations to consider calibration of future models.

The waste rock wetting analyses discussed in this memorandum are considered to be reasonable for the MacLellan and Gordon sites at the feasibility stage. Field data should be collected to refine the analyses at a later stage in the Project.

1.0 INTRODUCTION

The Lynn Lake Gold Project (LLGP; or "the Project") consists of two primary deposit sites, which are both located near Lynn Lake, Manitoba: the 'Gordon' site and the 'MacLellan' site. Alamos Gold Inc. (Alamos) intends to construct (redevelop), operate and eventually close/reclaim open pit gold mines at both these historical mine sites. The Gordon site is located approximately 55 kilometres (km) east of Lynn Lake, Manitoba (by vehicle), and the MacLellan site is located approximately 8 km northeast of Lynn Lake (by vehicle) (Map 1, Appendix A). Lynn Lake is located approximately 820 km northwest of Winnipeg.

This Hydrology Water Balance and Water Quality Technical Modelling Report (TMR) for the MacLellan site has been prepared to assess the potential effects of the construction, operation, closure and post-closure phases of the Project on surface water resources (water quantity and water quality) at the MacLellan site. The TMR considers the MacLellan site components of the Project, baseline data collected for the Project since 2015, and comments received from agencies, Indigenous communities, and other stakeholders.

To evaluate the effects of the Project, a water balance and water quality model (WBWQM) has been developed for the MacLellan site to:

- Estimate the quantity and quality of surface water runoff associated with the Project including the open pit, mill feed storage and crushing plant, ore stockpiles, overburden stockpile, mine rock storage area (MRSA), and TMF during all phases.
- Predict the quantity and quality of water that will be discharged to the environment during all phases.
- Estimate quantity and quality of surface water in the environmental receptors for baseline condition and during all phases.
- Aid in the development of the conceptual closure plan for the Project.

This TMR, and a companion TMR conducted for the Gordon site (Stantec 2020a), form part of the supporting documentation for the Environmental Impact Statement/Environmental Assessment completed for the Project.

1.1 PROJECT BOUNDARIES

1.1.1 MacLellan Project Development Area (PDA)

The MacLellan Project Development Area (PDA) encompasses the immediate area in which Project activities and components may occur plus a 30-metre (m) buffer. It is the anticipated area of direct physical disturbance associated with the construction and operation of the Project. The historical MacLellan site has been in a 'care and maintenance' phase since 1989 with very little reclamation having taken place. The site consists of a 4.6 km gravel access road, abandoned power transmission line, infrastructure from the former underground mine, such as a headframe, hoist house, shaft, access ramp, maintenance and other storage buildings, core shack and racks, vent raise, and mine water settling ponds. The size of the MacLellan PDA is approximately 11.2 km^2.

1.1.2 MacLellan Local Assessment Area (LAA)

The MacLellan Local Assessment Area (LAA) includes the PDA, and watercourses and lakes potentially affected by the Project (Map 1-2, Appendix A). Alamos proposes to develop mine infrastructure at the MacLellan site, including a central ore milling and processing plant, associated infrastructure, mill feed storage and crushing plant, ore and overburden stockpiles, a MRSA, open pit and a TMF. The existing 4.6 km access road will be used to access the site. Upgrades to the existing access road will be required, which will involve the removal of existing granular and placement of new material and compacted granular. The existing side ditches will be cleared or reconstructed based on a suitable design. With the proposed development of this site, the existing approximately 48 m tall headframe, hoist house and maintenance building will be demolished. The LAA represents the extent of the WBWQM. The size of the MacLellan PDA is approximately 126.9 km^2.

1.1.3 Regional Assessment Area (RAA)

The MacLellan LAA is one small component of the Regional Assessment Area (RAA). The RAA represents an area of approximately 9,929 km^2. The RAA includes the drainage area that encompasses the PDAs, LAAs, of both Project sites and the streams and lakes that drain the LAAs to a common downstream location (i.e., Granville Lake). It also includes upstream lakes and streams in the Keewatin River watershed to provide regional context for the lakes and streams within the LAAs and has been defined to allow assessment of potential cumulative effects with past, present, and reasonably foreseeable future projects. The RAA is not included in the MacLellan model domain, beyond the MacLellan LAA.

1.2 PROJECT PHASES AND COMPONENTS

Alamos proposes to develop mine infrastructure at the MacLellan site, including an open pit, central ore milling and processing plant, associated mining infrastructure, ore and overburden stockpiles, a MRSA, and a TMF. The existing access road will be used to access the site.

1.2.1 Mine Life Phases and Mine Plan

For modelling purposes, the third Project phase, decommissioning/closure, was sub-divided into two sub-phases of active closure and post-closure. On this basis, the phases of the Project considered in the WBWQM included construction, operation, active closure, and post-closure. Each phase is described in Table 1-1, including the time lengths for each.

Table 1-1 Summary Table of Each Model Phase

Phase	Time Frames Incorporated into the Model	Description
Baseline	Before Year -2	Mine activity does not occur during the period. The baseline time period is extended in the model to allow reservoirs within the model to reach steady state conditions.
Construction	Year -2 – Year -1 (2 years)	During this phase the following activities will be done: site preparation, physical construction and equipment installation, and commissioning.
Operations	Year 1 – Year 13 (13 years)	During this period the open pit will be developed, a MRSA will be constructed, ore will be processed, and the mill plant and TMF will be operational
Active Closure	Year 14 – Year 19 (6 years)	During this period, the MRSA will be recontoured and reclaimed and the open pit will be allowed to flood. The mill plant will be decommissioned and the TMF will be reclaimed and will only receive only natural inflows.
Post-Closure	Year 19 – Year 128 (109 years)	During this period, the collection pond will drain to the open pit, which will then discharge to the environment, if water quality is suitable. Other discharges include groundwater from the MRSA. The TMF will receive only natural inflows.

1.2.2 Project Components

In this section, individual Project components and catchment areas at the MacLellan site are discussed below and shown on Map 1-3 (Appendix A).

1.2.2.1 Proposed Mine Components

Open Pit. The open pit will be developed. The total quantity of material to be excavated from the MacLellan open pit during Project mine operations is approximately 266 Mt; this includes 26.9 Mt of ore (Q'Pit 2019). The anticipated depth of the MacLellan open pit is approximately 450 m. The open pit will be developed in a series of benches based on the pit design parameters with drilling and blasting completed on each bench. The pit slopes will be designed based on industry standards and the results of site-specific geotechnical investigations. The proposed mine operation is a conventional open pit with shovel and truck removal of the mine rock and ore produced during blasting. Ramp widths will be designed to accommodate the deployed type and size of the mine equipment and vehicles.

Mill Feed Storage and Crushing Plant – The run-of-mine (ROM) ore from both sites will be transported to a pad directly adjacent to the ore milling and processing plant at the MacLellan site for short-term storage before it is used as feedstock for the plant. Ore will be transported to the ore milling and processing plant by a conveyor system. Potential dust emissions will be reduced through dust containment (e.g., enclosure) and collection systems.

Ore Stockpiles, Overburden Stockpiles, and Mine Rock Storage Areas – Some ore will be stockpiled for future processing at the MacLellan site. One ore stockpile area is planned for the MacLellan site, located south of the mill, and will be approximately 115,500 m^2 in area.

The MacLellan site will also contain stockpile areas for removed overburden and mine rock. The overburden stockpile area is proposed to be located to the west of the MRSA. Table 2-3 provides the estimated maximum volumes of each material at the MacLellan site.

Table 2-2 Approximate Quantity of Mine Materials for the MacLellan Site

Project Site	Ore Stockpile		Overburden		Mine Rock	
	Tonnage (Mt)	Total Volume (Mm^3)	Tonnage (Mt)	Volume (Mm^3)	Tonnage (Mt)	Total Volume (Mm^3)
MacLellan	2.7	1.2	8.2	4.8	230.9	102.6

Notes: Mine rock and ore stockpiled swelled densities assumed to be 2.25 t/m^3. Overburden stockpile swelled density assumed to be 1.7 t/m^3. Mine rock volumes based on a bulking factor of 1.3. Overburden volumes based on a bulking factor of 1.1.

Table 2-4 provides the general characteristics of each stockpile/storage area (i.e., surface area, height, and overall slope).

Ore Milling and Processing Plant – The ore milling and processing plant is designed to process 7,500 t/day of ore, with a maximum potential process rate of 8,250 t/day. Ore will first be crushed in a two-stage crushing circuit comprising a primary jaw crusher, followed by a secondary cone crusher. Processing will continue with semi-autogenous grinding, then further grinding in a closed-circuit ball mill and cyclone circuit. Water demand at the ore milling and processing plant will primarily be supplied with reclaimed water from the TMF to reduce the need for fresh surface water demand. Dewatering water from the open pit and other mine contact water (i.e., any water, surface water or groundwater, that contacts mine workings or interacts with any mine rock material) will be collected in a site water management pond for management and/or treatment (if required) prior to discharge.

Tailings Management Facility – The TMF is proposed to be located approximately 1.5 km from the ore milling and processing plant. Water demand at the ore milling and processing plant will primarily be supplied with reclaimed water from the TMF to reduce the need for fresh surface water demand.

Water Supply and Distribution System - The source of fresh water for the MacLellan site will be the Keewatin River, located to the west of the MacLellan site. An intake system will supply water to the fresh/fire water tank at the plant. Maximum freshwater requirements at plant start-up are anticipated to be be 312 m^3/h and normal requirements will be 40 m^3/h. The system will provide potable water for personnel working at the MacLellan site, for eyewash, safety shower, personal hygiene, and drinking water. Treated water is anticipated to be stored in an on-site tank at the MacLellan site with water distribution providing potable water to the buildings at the MacLellan site. Raw water will be used for non-potable use such as fire water.

Sewage Treatment – The average sanitary wastewater flow rate will be approximately 60,000 L/d. A package treatment plant will be required with a discharge consisting of an outfall pipe and diffuser to the selected surface water receiver. The sewage treatment requirements and discharge criteria have not been developed at this stage ad were not included in the MacLellan WBWQM.

2.0 MODELLING APPROACH

The WBWQM was constructed using GoldSim simulation software with the contaminant transport (CT) module add-on extension. GoldSim software is commonly used in the mining industry to develop water balances and to predict water quality at user-defined modelling nodes by combining system dynamics with discrete event simulations. The model was run dynamically on a daily time step for the construction, operation, active closure, and post-closure phases. Results are presented and interpreted based on monthly averaged values.

The model is compartmentalized into WB and the WQM. The WB is calculated by incorporating defined inputs, such as inflow rates and outflow rates into the model. These inflows and outflows are based on precipitation rates, catchment and facility areas and volumes, groundwater inflows rates, operational water management strategies and the movement of materials within the site. The water quality predictions are calculated at the model nodes by integrating source term development (loading sources) into the WB.

The WB model consists of two sub-models to facilitate the evaluation of the “relative” impacts of the Project on the baseline environment. The first sub-model is the baseline water balance (BL-WB) and the second sub-model is the project water balance (PROJ-WB). The PROJ-WB was developed to predict changes to flow in the receiving environment and within the Project site during each phase of mine life. The BL-WB was developed to predict baseline flows across the site throughout the life of the mine (i.e. it assumes the Project does not occur), and it runs concurrently within the GoldSim platform with the PROJ-WB, to facilitate comparison between unimpacted and impacted conditions at each time step in the model.

Like the WB, the WQM consists two sub-models, the baseline water quality model (BL-WQM) and the project water quality model (PROJ-WQM) to facilitate comparison between non-Project and Project conditions.

Within the WBWQM, model nodes are representative of water monitoring stations. Creeks, streams or rivers are represented by a flow-through function in the WB, for which inflows equal outflows. Lakes are represented by reservoirs in the WB for which inflows equal outflows plus or minus storage. The model nodes are often represented as cells in the WQM; the flow through and within the cell is dependent on the WB, while loads can be added independently to the WBWQM. A load refers the amount of mass entering a model reservoir. The WB and WQMs are presented in Section 3.0 and Section 4.0, respectively.

Three climate scenarios were considered to evaluate the potential effects of the Project on surface water. The WB models and climate scenarios are discussed in more detail in Section 3.0. Two load scenarios are included in this report to evaluate the sensitivity of the source terms on the predictions and to aid in the development of a contingency planning (Section 4.0).

3.0 WATER BALANCE

3.1 GENERAL APPROACH

The following subsections present the approaches used for modelling water quantity with the water balance (WB). The WB provides estimates of streamflow and water levels from the existing watersheds, rivers and lakes. The WB model consists of two models:

Baseline Water Balance (BL-WB): The model contains the baseline condition or pre-mine stage, with no mine features. The model encompasses the LAA. The baseline model is calibrated using data from 2015-2016.

Project Water Balance (PROJ-WB): This model is built within the BL-WB and includes the proposed Project infrastructure and water management of the mine within the PDA as well as all other non-Project affected watersheds within the LAA.

The model includes various climate scenarios intended to define the potential range of flows and water levels considering uncertainty associated with inputs and assumptions. The general approach was to:

- Develop the BL-WB that includes lakes (reservoirs) for the sub-watersheds within the LAA.
- Calibrate the BL-WB to a period of measured climatic and hydrologic data in 2015 and 2016.
- Use the calibrated BL-WB to estimate the baseline streamflow and water levels for all climate scenarios.
- Develop the PROJ-WB by adding Project specific components and flows to the BL-WB.
- Estimate streamflows and water levels during all phases of the Project.
- Compare the BL-WB stream flows and lake water levels to the PROJ-WB predictions during all phases of the project for wet, dry and average conditions.

3.2 BASELINE WATER BALANCE STRUCTURE

This section describes the inputs used to calibrate the BL-WB. The BL-WB was developed to model the baseline conditions of the LAA. This includes watersheds within the PDA as well as all watersheds and sub-watersheds connected to the Keewatin River watershed. The BL-WB models the LAA without the Project and represents the baseline or pre-Project conditions.

3.2.1 Baseline Water Balance Conceptual Model

The BL-WB is developed to predict streamflow for sub-watersheds and lake levels within the LAA of the MacLellan site. The overall LAA for MacLellan n is shown in Map 3-1, with more detail on the MacLellan site watersheds shown on Map 3-2. Details of the BL-WB input parameters and the calibration of the model are provided below in Section 3.2.3 and Section 3.2.4.

For the BL-WB model the Snowmelt-Runoff Model (SRM) was selected to simulate the hydrologic response of the watersheds within the LAA. The model was run on a daily time step and calculates the runoff from each watershed and integrated into lake water balance model for lakes in the modelled area. For each lake a stage-volume and stage-area relationship was used to balance the water in the lake and determine lake levels for model calibration and lake volumes for water quality modelling. The model provides an integrated hydrology and water balance. Table 3-1 presents a list of the watersheds modelled for the MacLellan site. Figure 3-1 presents the conceptual model for how the watershed and the lakes are connected in the model.

The BL-WB was calibrated iteratively to measured stream flow and lake water level data during 2015 and 2016 at a number of hydrometric stations shown on Map 3-2 (Stantec 2017a). Statistical assessment of the BL-WB was performed to measure the model's performance. Detailed model inputs, calibration parameters and statistical assessment of the calibration is provided Section 3.2.3 and Section 3.2.4.

3.2.2 Baseline Water Balance Description

The SRM is designed to simulate streamflow at a daily timestep (additional details are provided in Martinec et al. 2008) in the BL-WB. Streamflow generated from snowmelt and rainfall is computed, using the following equation (*Equation 3-1*):

$$Q_{n+1} = [C_{Sn}.a_n(T_n + \Delta T_n)S_n + C_{Rn}P_n]\frac{A.10000}{86400}(1 - K_{n+1}) + Q_nK_{n+1} \quad \textit{Equation 3-1}$$

Where:

Q = average daily discharge ($m^3 s^{-1}$)

C = runoff coefficient; expresses losses to streamflow as a ratio (runoff/precipitation), with C_S referring to snowmelt and C_R to rain

a = degree-day factor (cm °C^{-1} d^{-1}) indicating the snowmelt depth resulting from 1 degree-day

T = number of degree-days (°C d)

Δ T = the adjustment by temperature lapse rate when extrapolating the temperature from the station to the average hypsometric elevation of the basin or zone (°C d)

S = ratio of the snow-covered area to the total area

P = precipitation contributing to runoff (cm).

T_{CRIT} = threshold temperature that determines whether the precipitation is rainfall or snow. A threshold temperature is used to decide whether a precipitation event will be treated as rain ($T \geq T_{CRIT}$) or as new snow ($T < T_{CRIT}$). If precipitation is determined by T_{CRIT} to be new snow, it is kept on storage over the hitherto snow free area until melting conditions occur.

A = area of the sub-catchment [km^2]

K = recession coefficient indicating the decline of discharge in a period without snowmelt or rainfall:

n = sequence of days during the discharge computation period.

$\frac{10000}{86400}$ = conversion from cm·km^2 d^{-1} to m^3 s^{-1}

T, *S* and *P* are variables to be measured or determined each day, C_R, C_S are lapse rate to be determined, Δ *T*, T_{CRIT}, *K* and the lag time are parameters which are characteristic for a given basin or, more generally, for a given climate. The lag time is the time difference between the start of increasing temperatures and the corresponding increase in runoff from the basin.

All parameters with unknown values (S, C_R, C_S, *K, a)* were determined during the calibration process.

3.2.2.1 Lake Level and Lake Outflow

Where no stage-discharge relation was available for lakes in the LAA, the relation was estimated using *Equation 3-2*:

$$Qout = CD * (Lake\ Water\ Level - Ho)^{\ P} \qquad \textit{Equation 3-2}$$

where*:*

Q_{out} = Lake Outflow (m^3/s)

CD = Lake Coefficient

H_o = Minimum water level for lake outflow (m^3/s)

P = Power Coefficient (m^3/s)

All parameters with unknown values (*CD*, *Ho*, *P)* were determined during the calibration process.

3.2.2.2 Baseline Water Balance Calibration

Models are mathematical approximations of physical systems. Calibration is a process wherein certain parameters of the model are altered in a systematic fashion and the model is run iteratively until the computed values matches the observed values within a range that is considered acceptable. The GoldSim model optimization tool was used for model calibration of the SRM. Model performance is measured in terms of the ability to reasonably predict key response variables such as streamflow and lake level. Statistical assessment of the calibrated hydrology model was performed to measure model performance. The following statistical parameters were used in this study:

Nash-Sutcliffe Model Efficiency

The Nash–Sutcliffe model efficiency coefficient, was used to assess the predictive results (flow or lake level) of the BL-WB (*Equation 3-3*). The Nash–Sutcliffe model efficiency coefficient (*E*) is defined as (Nash and Sutcliffe, 1970):

$$\boldsymbol{E = 1 - \frac{\sum_{t=1}^{T}\left(Q_o^t - Q_m^t\right)^2}{\sum_{t=1}^{T}\left(Q_o^t - Q_{o,avg}\right)^2}} \qquad \textit{Equation 3-3}$$

Where:

Q_o is observed value

Q_m is modelled value

$Q_{o,avg}$ is average observed value

Generally, Nash–Sutcliffe coefficient ranges from $-\infty$ to 1 with a value of 1 indicating a perfect match of modelled value to the observed data (i.e., the closer the model efficiency to 1, the more accurate the model is). An efficiency of 0 indicates that the model predictions are as accurate as the mean of the observed data. An efficiency less than zero indicates that the observed mean is a better predictor than the model.

Correlation Coefficient

The Pearson's Correlation Coefficient (*R*) indicates the strength and direction of a linear relationship between the model output and observed values. It is obtained by dividing the covariance of the two variables by the product of their standard deviations (*Equation 3-4*).

$$\boldsymbol{R} = \frac{\sum_{t=1}^{T}\left(Q_o^t - Q_{o,avg}\right)\cdot\left(Q_m^t - Q_{m,avg}\right)}{\sqrt{\sum_{t=1}^{T}\left(Q_o^t - Q_{o,avg}\right)^2 \cdot \sum_{t=1}^{T}\left(Q_m^t - Q_{m,avg}\right)^2}}$$

Equation 3- 4

where $Q_{m,avg}$ is average modelled value for the simulation period, and other variables are as previously defined.

Further details on inputs and calibration are discussed in Section 3.2.3 and Section 3.2.4.

3.2.3 Baseline Water Balance Inputs

3.2.3.1 Climate

Historical climate data were gathered from the Environment and Climate Change Canada (ECCC) National Climate Data and Information Archive (ECCC 2019). Climate data relevant to the Project area is available from four ECCC meteorological stations: Lynn Lake Airport (Climate ID 5061646), Lynn Lake (Climate ID 5061648), Lynn Lake (Climate ID 5061645), and Lynn Lake Reference Climate Station (RCS) (Climate ID 5061649). These four stations were chosen because of their proximity to the Project area and relatively long period of record. Stations 5061646, 5061648, and 5061645 are located at the Lynn Lake Airport and Station 5061649 is located just south of the airport. The Lynn Lake climate stations encompass data from 1968 to 2005 (5061646), 2005 to 2014 (5061648), and 2010 to 2017 (5061645 and 5061649). Together these stations have a continuous record going back more than 40 years; this record was used to generate historic temperature and precipitation. Stations 5061645 and 5061649 are currently in operation. Daily temperature, precipitation, and snowfall data was downloaded and used for input.

Additional analysis of climate data is provided in Stantec (2017b). The summary of the average temperature, precipitation, and snow on ground data for the 2015 and 2016 water years and climate normals (1981-2010) at the Lynn Lake stations (the combined record of ECCC stations 5061645 and 5061649) is provided in Table 3-2.

The 2015 and 2016 daily climate data were used for model calibration periods. The historical climate data were used to develop the average, 25-year wet and 25-year dry climate scenarios for the model simulations (Section 3.3.2). The Prairie Farm and Rehabilitation Administration (PFRA) estimated the Lynn Lake annual lake evaporation rate to be 476 mm based on historical gross evaporation data (PFRA 2002), with the

maximum monthly evaporation rate occurring in July at 141.2 mm (Table 3-3). The monthly lake evaporation data were used in the lake and pond (open pit and collection ponds) water balance models.

3.2.3.2 Watershed Areas

A geographic information system mapping approach was used to delineate sub-watersheds for the MacLellan Site. Site specific Light Detecting and Ranging (LiDAR) data at approximately 2 m x 2 m resolution was used. For areas where LiDAR coverage was not available, digital elevation model data from GeoBase (Natural Resources Canada 2014) at approximately 20 m x 20 m resolution was used. A naming system was designated for all reaches in the MacLellan LAA; where *ws* stands for watershed and *sws* stands for sub-watershed. Table 3-4 presents watershed characteristics.

Table 3-4 Physiographic Characteristics of Watersheds in the MacLellan Site

Watershed Name	Sub-Watershed Name	Waterbodies and Project Components within Watershed or Sub-Watershed	Area (km²)	Minimum Elevation (m)	Maximum Elevation (m)	Lake Coverage (%)	Tributary to
ws-KEE4	n/a	Goldsand Lake and Burge Lake	1310	339	443	23	Keewatin River
ws-KEE3.3	n/a	Keewatin River	3.4	337	364	0.81	Keewatin River

ws-KEE3-DOT1	n/a	Dot Lake	7.2	336	368	1.4	Keewatin River

Table 3-4 Physiographic Characteristics of Watersheds in the MacLellan Site

Watershed Name	Sub-Watershed Name	Waterbodies and Project Components within Watershed or Sub-Watershed	Area (km²)	Minimum Elevation (m)	Maximum Elevation (m)	Lake Coverage (%)	Tributary to
ws-KEE3.2	n/a	Keewatin River	2.3	335	367	0.99	Keewatin River
ws-KEE3.1	n/a	Keewatin River	3.0	319	351	0.98	Keewatin River
ws-LYN1	n/a	Lynn River	470	318	444	0	Keewatin River
ws-COC2-LOB2-MIN4 (East MacLellan site watershed)	sws-COC2-LOB2-MIN5	Unnamed lake COC2-LOB2-MIN5-A1 Tailings Management Facility	6.3	330	363	3	Unnamed stream COC2-LOB2-MIN5 to Minton Lake
	sws-COC2-LOB2-MIN4	Minton Lake Tailings Management Facility	5.7	329	363	29	Unnamed stream COC2-LOB2-MIN3 to unnamed lake COC2-LOB2-MIN2 to Cockeram River
ws-KEE1	n/a	Cockeram Lake, Carr Lake, Huet Lake, Arbour Lake, Desieyes Lake, Lobster Lake, Unnamed lake COC2-LOB2-MIN2	189	311	382	0	Moses Lake

Notes:
n/a – this watershed was not divided into subwatersheds
n/a* - no lake coverage or proposed project components exist within this subwatershed
"-" – available LiDAR data does not cover the entire watershed and therefore lake and wetland coverage cannot be calculated

3.2.3.3 Lake Bathymetry

Lake bathymetric data were collected at key lakes. Sites were chosen based on their proximity to the proposed mine operations and potential to be physically altered by the proposed development. Within the MacLellan LAA, sites included Dot Lake and Minton Lake. Additional details of the bathymetric field program are presented Stantec (2017a). Lake bathymetric data is used in in the development of the BL-WB. Lake volume-elevation and lake area-elevation relationships were established using the lake bathymetric data and topographic information surrounding the lake and used as an input to the lake water balance model. The results of lake surface area and volume for average lake levels in the hydrology model for the MacLellan site are presented in Table 2-5.

Table 3-5 Lake Surface Areas and Volumes for the MacLellan LAA

Lake Name	Surface Area (m^2)	Volume (m^3)
Burge Lake	4,747,961	No measured depth
Cockeram Lake	21,051,000	63,153,000
Minton Lake	1,666,440	2,525,880

3.2.3.4 Measured Streamflow and Water Level

The locations and watersheds of the hydrometric stations that are used for model calibration at MacLellan site are shown in Table 3-6**.** Five stations (QM01, QM03, QM05, QM06 and QM08) had sufficient data to allow a stage-discharge relationship to be developed and subsequent calculation of discharge for the 2015 and 2016 monitoring period (Stantec 2017a). The remaining stations are limited to stage data and point measurements of discharge. A more thorough explanation of the data limitations and field data analysis are provided in Stantec (2017a). The measured discharge at the five monitoring stations were used for BL-WB calibration. The drainage areas in Table 3-6 differ from the catchment areas in Table 3-1 in that those listed in Table 3-6 represent the cumulative watershed area the drains to the hydrometric station.

Table 3-6 Geographic and Physiographic Details for the MacLellan Hydrometric Monitoring Stations Used in the Model

Station	UTM Coordinates (Zone 14V)	Period of Operation	Available Parameters for model calibration	Drainage Area (km^2)	% Lakes	Description
QM01	379675 E 6310698 N	May 26, 2015 - present	Discharge	1,310.1	23.0	Keewatin River, upstream of the project area.
QM03	380709 E 6306104 N	May 25, 2015 - present	Discharge	1,333.7	22.8	Keewatin River, immediately downstream of the proposed open pit.
QM05	381934 E 6303916 N	June 1, 2015 - present	Discharge	470.4	10.0	Lynn River, above the confluence with the Keewatin River. The objective of this station is to measure flows into Cockeram Lake that are not influenced by the Project or the Keewatin River.
QM06	381889 E 6304247 N	May 27, 2015 - present	Discharge	1,344.8	22.7	Keewatin River, downstream of the potential PDA and upstream of the confluence with the Lynn River. The objective of this station is to measure flows into Cockeram Lake that may be influenced by the Project.
QM08	388377 E 6296094 N	May 31, 2015 - present	Discharge	2,004.5	19.1	Outlet at the south end of Cockeram Lake

3.2.3.5 Groundwater

Groundwater discharge to the lake and lake discharge to the groundwater system were predicted for Minton Lake for baseline condition using a hydrogeological model presented in Stantec (2020b). The steady-state calibrated groundwater flow model was used to quantify baseline groundwater levels and flow and groundwater discharge to the receiving environment under baseline conditions.

The groundwater discharge to Minton Lake and lake discharge rates to the groundwater were used as an input to BL-WB and PROJ-WB. The estimated groundwater discharges to the lakes under baseline conditions is presented in Table 3-7.

Groundwater also discharges to rivers as baseflow. Baseflow estimates in the model are based on inflows calibrated in the BL-WB using the SRM model.

Table 3-7 Estimated Groundwater Discharges for Minton Lake under Baseline Conditions (Stantec 2020b)

Phase	Groundwater to Lake (m^3/s)	Lake to Groundwater (m^3/s)	Net Groundwater Inflow (m^3/s)
Baseline	0.0390	0.0360	0.0030

3.2.4 Baseline Water Balance Calibration

3.2.4.1 Model Calibration

The BL-WB was calibrated based on streamflow and lake water level measurements at monitoring stations described in Section 3.2.3 for the period June 2015 to September 2016.

The overall calibration strategy was to compare the model results to observed datasets for the period of record (Stantec 2017a). The calibration was done by generating and comparing simulated and observed monthly and daily average streamflow and simulated and observed daily average lake water levels. Precipitation from June 1, 2015 to September 31, 2016 were used as inputs into the model. The model results were compared to observed values and the parameters comprising the SRM were adjusted until a satisfactory calibration was obtained.

During model calibration, runoff coefficient (*C*), recession coefficient (*K*) and degree-day factor (*a*) were adjusted for each watershed; and lake coefficient (*CD*), minimum water level for lake outflow (*Ho*) and Power Coefficient (*P*) were adjusted for each lake. Runoff coefficient values are different during rain and snowmelt periods for a given watershed. Snowmelt period is the time where the temperature is below threshold temperature that determines whether the precipitation is rainfall or snow. The rain period is the time where the temperature is above threshold temperature.

3.2.4.2 Calibration Result

Streamflow

As indicated above, streamflow data were only available for five of the monitoring stations (QM01, QM03, QM05, QM06 and QM08). The streamflow data at these stations were used to calibrate the hydrology model for MacLellan site.

Figure 3-2 and Figure 3-6 show monthly and daily measured and simulated streamflow at the five monitoring stations. The model captures the seasonal patterns of the observed streamflow. Statistical assessment of the model performance is presented in Section 3.2.4.3.

3.2.4.3 Statistical Assessment

Table 3-8 shows the Nash–Sutcliffe coefficient (*E*) and Pearson correlation coefficient (R) for the average monthly and daily discharge at QM01, QMO3, QM05, QM06 and QM08. As shown in this table, *E* for the monthly and daily average discharges at all five stations is greater than 0.78, and correlation coefficient s are greater than 0.90, representing a strong match between the modelled and observed data.

Table 3-8 Hydrology Model Performance Parameters: MacLellan Site

Parameter	Monthly Discharge				
	QM01	QM03	QM05	QM06	QM08
Nash-Sutcliffe Coefficient (E)	0.95	0.94	0.83	0.93	0.94
Correlation Coefficient (R)	0.97	0.97	0.97	0.97	0.97
	Daily Discharge				
	QM01	QM03	QM05	QM06	QM08
Nash-Sutcliffe Coefficient (E)	0.89	0.88	0.78	0.82	0.89
Correlation Coefficient (R)	0.94	0.94	0.94	0.91	0.95
	Lake Level				
	QM01	QM07	QM08		
Nash-Sutcliffe Coefficient (E)	0.89	0.09	0.63		
Correlation Coefficient (R)	0.94	0.43	0.92		

3.2.4.4 Application of Baseline Water Balance

With calibration of BL-WB complete, the PROJ-WB was constructed. The PROJ-WB will be used to assess potential effects of the Project on surface water flow and lake levels. This is accomplished through comparison of BL-WB streamflows to PROJ-WB streamflows (or BL-WB lake levels to PROJ-WB lake levels) during all phases of the Project (construction, operation, active closure, and post-closure phases).

3.3 PROJECT WATER BALANCE STRUCTURE

This section presents the conceptual model inputs and assumptions used to develop the PROJ-WB and includes a discussion of baseline catchments that change due to the Project as well as a discussion of the mine site and operational flows. The modelling assumptions used in watersheds that change as a result of the Project are described below.

3.3.1 Project Water Balance Conceptual Model

The PROJ-WB includes components of the BL-WB and details related to the overall Project mine plan from construction, operation, closure and post-closure.

The sub-watershed areas affected by site infrastructure were subtracted from the baseline watershed areas for each sub-watershed, and the streamflow from the unaffected watershed is estimated using the BL-WB. The PROJ-WB was used to estimate streamflow and lake level during all phases of the Project.

Figure 3-7 presents the model structure of the PROJ-WB and highlights the model nodes, the MacLellan PDA, and identifies which nodes are associated with either contact water (water that has contacted the Project) or non-contact water (water not affected by the Project).

For conservatism in the model, it is assumed that the catchment area for all mining features are fully realized at start of construction. This means that contact water from stockpiles start flowing to the collection ponds at the beginning of construction.

The following sections present a summary of the Project, schedule and the overall modelling approach used for the PROJ-WB. Wherever possible, conservative assumptions have been included in the modelling approach for the purposes of predicting potential environmental effects.

The Project components (described in Section 2.0) in the PROJ-WB include: the open pit, mill and processing plant, TMF, MRSAs, ore stockpile and overburden storage areas. It is assumed that the above facilities will have external drainage controls that prevent natural drainage from coming into contact with Project components and becoming contact water. The model differs from the BL-WB in that in areas with Project facilities the model uses runoff coefficients in place of the SRM.

Catchment areas for the open pit, overburden storage area, ore stockpile and MRSAs, mill and process plant, and TMF were delineated based on the site plan (Map 1-2). Using existing ground surface topography, the catchment areas were delineated where seepage from the bases of the MRSAs, ore stockpile and overburden storage areas are expected to report to the collection ditches and then to the collection pond. It is assumed that these catchment areas will not change during operation and active closure.

The model was run dynamically on a daily time step and results are presented on monthly reporting period for average, 25-year wet and 25-year dry climate scenarios (Section 3.3.2.1) for the construction, operation, active closure and post-closure phases.

Conceptual models showing the interactions of the Project components during operation, active closure and post-closure are presented in Figure 3-8 to Figure 3-10. To simulate closure, the PROJ-WB was extended to run until Year 128.

3.3.2 Project Water Balance Inputs

3.3.2.1 Climate Scenarios

An evaluation of climate and hydrologic data for the Project was previously presented by Stantec (2017a). For the PROJ-WB, precipitation data from Environment Canada's Lynn Lake climate station (Climate ID 5061646) were used to generate the climatic conditions for average, 25-year wet, and 25-year dry conditions.

The climate normals data for period 1981 to 2010 were used to represent average climatic conditions. For the 25-year wet and 25-year dry return climate scenarios, annual precipitation data was fit to the log normal probability distribution. The result of the 25-year dry and 25-year wet year precipitation conditions are provided in Table 3-9. Average annual lake evaporation presented in section 3.2.3.1 was used.

Table 3-9 Average Climate, Wet-Year and Dry-Year Precipitation Conditions

Parameter	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Year
Average Year Total Precipitation (mm)	20.3	16.3	19.8	24.1	37.3	61.8	85.4	68.8	61	37.6	26.8	18.8	478
25-Year Dry Precipitation (mm)	14.6	11.7	14.3	17.4	26.9	44.5	61.5	49.6	44.0	27.1	19.3	13.5	344
25-Year Wet Total Precipitation (mm)	27.8	22.4	27.1	33.0	51.1	84.7	117.1	94.3	83.6	51.6	36.7	25.8	655

3.3.2.2 Runoff Coefficients

For areas changed by Project infrastructure, runoff coefficients were used to transform precipitation into surface runoff considering relief, surface storage, vegetation cover, evaporation, evapotranspiration, and infiltration losses. Runoff represents all surface water flows originating from overland flow, direct precipitation to waterbody surfaces, interflow and groundwater discharge. Table 3-10 presents the runoff coefficients used in the site water balance model for various mine infrastructure facilities.

Table 3-10 Facilities Runoff Coefficients used in PROJ-WB

Parameter	Runoff Coefficient
Ponds and Wet Tailings Beach	1.0
Dry Beach	0.7*
Open Pit Wall	0.95
Natural Ground	0.40
Disturbed/prepared Ground	0.85
Overburden	0.40
* Dry Beach runoff coefficient includes beach recharge that reports to the TMF pond	

Climate in the Project area is continental with lengthy cold winters. Very little surface runoff occurs during the winter months. Accumulated winter precipitation (snow) is released largely as surface runoff during the spring freshet and is accounted for in the runoff factors presented in Table 2-10. This process is modelled by applying a monthly precipitation-runoff factor that accounts for how much precipitation becomes runoff in a particular month (Table 3-11). The monthly precipitation-runoff factor was developed using the approximate monthly values of snowmelt and runoff generated by the SRM during baseline conditions and using the precipitation data. Available-runoff represents the current month's precipitation plus the remaining fraction of water from the previous month's precipitation that did not became actual-runoff, as it accumulated as snow (thus not available for runoff).

The surface runoff from the mine infrastructure facilities is estimated as the product of precipitation, precipitation-runoff factors and runoff coefficients. The balance of the precipitation that is not allocated to runoff is carried over to the next month.

Table 3-11 Precipitation-Runoff Factors used in PROJ-WB

Month	Precipitation-Runoff Factor	Month	Precipitation-Runoff Factor
January	0.01	July	1.0
February	0.01	August	1.0
March	0.01	September	0.95
April	0.01	October	0.50
May	0.40	November	0.05
June	0.98	December	0.01

3.3.2.3 Open Pit

Model inputs to the open pit include groundwater inflow, precipitation and runoff that occur within the open pit and evaporation losses from ponded water within the open pit. During operation, groundwater inflow, precipitation and runoff that accumulates in the open pit will be pumped to the collection pond.

This water will require management as part of open pit dewatering. The following provides a summary of the model assumptions and input parameters.

Groundwater Inflow

Groundwater inflow rates to the open pit were predicted using the numerical groundwater flow model developed for the Project (Stantec 2020b). Figure 3-11 shows the monthly average groundwater inflow rates to the open pit during construction and operation. Due to open pit wall freeze up, groundwater inflow rates are generally low in winter comparing to spring, summer and fall months.

Open Pit Dewatering Rates

In the PROJ-WB, open pit dewatering rates were calculated for each mining year. During operation, water from open pit dewatering will be pumped to collection pond. During freshet, 75% of open pit dewatering will be pumped to the TMF.

Open Pit Filling

Dewatering of the open pit is terminated with the end of the operation stage (Year 13), after which water levels within the open pit are allowed to recover as a result of groundwater inflow, direct precipitation, and runoff. The groundwater inflow rates were modelled using the three-dimensional groundwater flow model (Stantec 2020b) and are presented in Figure 3-12.

To accelerate the filling of the open pit and to deal with overflow from TMF, water from the TMF and collection pond will be directed to the open pit beginning at the closure stage until the open pit is filled to the design elevation of 330 m above sea level (masl). After the open pit is full, open pit overflow will be directed to the Keewatin River.

3.3.2.4 Site Catchment Areas

Catchment areas for runoff and seepage collection from the open pit, mill, ore stockpile, MRSAs and overburden storage area were obtained from site water balance model (Golder 2020) during construction and operation periods. The areas for plant site, overburden, open pit, MRSA, plant site stockpile, top soil stockpile and collection pond are summarized in Table 3-12 and the timing when each area is active in the model. It was conservatively assumed that all surface water in the catchment areas is contact water and requires management. The contact water is directed either to the collection ponds via collection ditches or to the open pit and TMF.

3.3.2.5 Project Changes to Watershed Areas

Streamflow during operation, active closure and post-closure were simulated using the PROJ-WB. In order to integrate the hydrology and site water balance models, the site infrastructure areas were subtracted from the baseline watershed area for each sub-watershed that are affected by the project. Streamflow for the unaffected watershed areas were estimated using the BL-WB. Streamflow for the affected areas were estimated using the PROJ-WB. Table 3-13 presents the affected and unaffected area in each sub-watershed for MacLellan Site.

Table 3-12 Catchment Areas (m^2) used in Water Balance (Golder 2020)

Mine Year	Plant Site			Overburden Stockpile			Open Pit			Mine Rock Stockpile			Plant Site Stockpiles			Topsoil Stockpile			Collection Pond	
	Total	Prepared Ground	Natural Ground	Total	Overburden	Natural Ground	Total	Pit	Natural Ground	Total	Stockpile	Natural Ground	Total	Stockpile	Natural Ground	Total	Stockpile	Natural Ground	Total	Pond Surface

Table 3-13 Summary of Watershed Area Changes within the MacLellan Site due to the Project

Watershed Name	Sub-Watershed Name	Waterbodies and Project Components within Watershed or Sub-Watershed	Baseline Area (km²)	Area Affected by Project (km²)	Percent Area Affected by Project (% of decreased Baseline Area)	Tributary to
ws-KEE3 (West MacLellan site watershed)	sws-KEE3-PAY2	Payne Lake	3.3	0.24	7.3%	Unnamed stream KEE3-PAY1 to Keewatin River
	sws-KEE3-PAY1	n/a*	4.6	0.08	1.7%	Keewatin River
	sws-KEE3-4	Keewatin River	0.71	0.003	0.4%	Keewatin River
	sws-KEE3-C1	Mine Rock Storage Area and Overburden Stockpile	0.32	0.067	21%	Keewatin River
	sws-KEE3	Keewatin River Proposed Pit	2.6	0.59	23%	Keewatin River
	sws-KEE3-B1	East Pond Processing Plant, Proposed Pit, Mine Rock Storage Area, Ore Stockpile, and Overburden Stockpile	5.7	3.66	64%	Keewatin River
	sws-KEE3-A1	Keewatin River	1.9	0	0%	Keewatin River
ws-COC2-LOB2-MIN4 (East MacLellan site watershed)	sws-COC2-LOB2-MIN5	Unnamed lake COC2-LOB2-MIN5-A1 Tailings Management Facility	6.3	1.5	24%	Unnamed stream COC2-LOB2-MIN5 to Minton Lake
	sws-COC2-LOB2-MIN4	Minton Lake Tailings Management Facility	5.7	0.85	15%	Unnamed stream COC2-LOB2-MIN3 to unnamed lake COC2-LOB2-MIN2 to Cockeram River

Notes:

The catchment areas for watersheds ws-KEE4, ws-KEE3.3, ws-KEE3-DOT1, ws-KEE3.2, ws-KEE3.1, ws-LYN1, and ws-KEE1 are not affected by Project components and are not listed here.

n/a* - no lake coverage or proposed project components exist within this sub-watershed

3.3.2.6 Project Changes to Groundwater Flow

The groundwater that discharges to Minton Lake is predicted to change throughout construction, operations, and closure. Groundwater discharge to Minton Lake was predicted using the groundwater model (Stantec 2020b). The estimated groundwater discharges to the lakes during the Project is presented in Table 3-14.

Table 3-14 Estimated Groundwater Discharges to Minton Lake during Construction, Operation and Active Closure Phases - With Ditches

Phase	Groundwater to Lake (m^3/s)	Lake to Groundwater (m^3/s)	Net Groundwater Inflow (m^3/s)
Construction	0.040	0.036	0.004
Operation	0.039	0.035	0.004
Active Closure	0.039	0.036	0.003

The overall baseflow rates for KEE3-B1 tributary, KEE3-Pay1 tributary, and the Keewatin River are predicted using the SRM; however, the percentage change to baseflow was predicted using the groundwater model (Stantec 2020b). The percentage change to predicted baseflow rates was calculated and incorporated into the PROJ-WB (Table 3-15). The change in the Keewatin River was provided at model node QMO3 so that predictions remained conservative.

Table 3-15 Change to Baseflow at Model Nodes during Construction, Operation and Active Closure Phases

Phase	KEE3-PAY1 (m^3/s)	KEE3-B1 (m^3/s)	QM03 (m^3/s)
Construction	0.0	0.0	0.006
Operation	0.0022	0.0011	-0.001
Active Closure	0.0025	0.0017	-0.0001

3.3.3 Mine Rock Storage Areas

A conceptual model of flow through the MRSA was developed to model evaporation, infiltration, and runoff in the MRSA through all mine phases (Stantec 2020c). Key inputs and assumptions for the analysis were:

- The MRSA is divided in two components: slopes and central portion.
- The central portion is sub-divided in 2 sub-surface flow components: macropore flow and micropore flow.
- Infiltration is split between lateral seepage (toe seepage) and groundwater recharge at the base of the MRSA.

Figure 3-13 presents a schematic of the flow pathways for water around and within the pile. A simple evaporation, runoff and infiltration model was used for the slopes, the macro/micropore flow paths were not modelled. It is assumed that this process will have less effect on flows, particularly at the toe of the slope where the thickness of the slope approaches zero.

The flow behavior through the MRSA depends on the wetting phase, which is dependent on time and whether the MRSA is covered. Flow behavior through the MRSA depends on the following temporal conditions:

- *Wetting*: time during which a wetting front is progressing through the MRSA. The mine rock is initially placed dry, and the wetting process continues over the years following placement. The wetting process was not modelled for the slope, for a similar reason that separate macro/micropore flow paths were not considered.
- *Wet*: the wetting front has broken through the base of the pile and the infiltration and unsaturated hydraulic conductivity profile of the material has reached an equilibrium. Steady state has been reached.
- *No-cover*: There is no cover over the MRSA.
- *Cover*: there is a cover over the MRSA. The wetting process continues when the cover is in place.

The stages of MRSA development are defined as follows:

I **Wetting + No-Cover**: occurs during construction, operations and closure.

II **Wetting + Cover**: occurs during the first 25 years of post-closure (Stantec 2020c).

III **Wet + Cover**: occurs following 25 years (i.e., after Stage II) of post-closure.

Table 3-16 outlines the proportion of total precipitation that is routed through the MRSA per the flow paths shown on Figure 3-13. Every division of flow is proportionally calculated using the percentages shown in Table 3-16, according to the wetting phase (I, II or III), and the stockpile section (slope, macropore, micropore).

The following example can be used to explain how the data from the table is used:

To calculate surface flow on the MRSA slope for the stage II (wetting + cover), in the table select:

- row: “Surface flow” (Flow 2)

- column section: “a.slope”

- column: “II”

Value = 60% - which is the percentage to be applied to the calculated Flow 1 (Effective precipitation).

Table 3-16 MRSA Water Balance

<table>
<tr><th rowspan="2">Process</th><th rowspan="2">Flow</th><th colspan="3">a. Slopes</th><th colspan="3">b. Micropores</th><th colspan="3">c. Macropores</th></tr>

</table>

Details of the MRSA water balance estimates is provided in the MRSA modelling memorandum (Stantec 2020c). Surface runoff and toe seepage are collected in the contact water collection ditches and directed to the collection pond. The efficiency of the ditches is assumed to be 100% and the recharge is lost to the environment.

3.3.4 Mill and Processing Plant

Inputs for production data for the process plant are presented in Table 3-17 and are based on data in Golder (2020).

Table 3-17 Mill Production and Model Input Data (Golder 2020)

Parameter	Rates	Units
Volume of water leaving the mill in tailings slurry	250,124	m^3/mon
Fresh water required for the mill	1,141	m^3/mon
Evaporation and spillage losses at the mill	2,501	m^3/mon

3.3.5 Tailing Management Facility (TMF)

The areas for the TMF used in the PROJ-WB are presented in Table 3-18 and were provided by Golder (2020). Water in the TMF is used in the model to meet mill demand until the end of Year 13. The TMF is a no discharge facility during operation. At closure and post closure, water from the TMF is directed to the open pit until the open pit is filled to the design elevation of 330 masl. Once the water level within the pit lake reaches this elevation, water from the pit will be overflow and discharge to the Keewatin River.

It is assumed that 20% of the beaches were wet and the remaining 80% of the beaches were dry (Golder 2020). From the total TMF prepared area, 75% represents the downstream dam face area (Golder 2020). The runoff from the wet and dry beaches are based on the runoff coefficients presented in Table 3-10.

Table 3-18 TMF Areas (Golder 2020)

Mine Year		Project Stage	TMF Area (m^2)				Total Prepared Ground (m^2)
			Total	Pond	Beach	Natural Ground	
-2	-0.34	0	0	0	0	0	0
-0.33	1	1	2,043,588	516,748	640,000	886,840	157,798
2	5	2	2,575,887	324,400	1,486,000	765,487	615,871
6	15	3	2,577,781	582,473	1,492,400	502,908	380,064

Tailings properties and TMF inputs are presented in **Table 3-19** and are from Golder (2020).

Table 3-19 Tailings Properties (Golder 2020)

Parameter	Stage 1	Stage 2	Stage 3
TAILINGS			
Volume of deposited tailings (m^3/day)	5,000	5,000	5,000
Groundwater seepage collected by Seepage Collection System and pumped back to TMF (m^3/day)	0	0	0
Seepage to environment (m^3/day)	423	423	423
Dead storage volume (m^3)	11,713	4,793	52,246
Pond maximum storage volume (m^3)	1,105,345	4,000,000	5,110,258

3.4 PROJECT WATER BALANCE RESULTS

3.4.1 Overview

The PROJ-WB combines the components of the BL-WB with components developed to model areas changed by the Project. The BL-WB provides estimates of streamflow for watersheds in the LAA under existing conditions. The PROJ-WB provides estimates of flow for the mine facility and incorporates the mine plan and water management features of the mine into the baseline environment. The PROJ-WB also incorporates results from groundwater modelling (Stantec 2020b) and runoff and seepage from key Project components. Runoff from the site infrastructure was estimated using modified model components developed for the PROJ-WB. The PROJ-WB was used to estimate streamflow and lake level during the construction, operation, active closure, and post-closure phases of the Project.

3.4.2 Baseline Water Balance Model Results

The calibrated BL-WB was used to model baseline flows and lake levels for the MacLellan LAA. The baseline streamflows for the average, 1:25 dry, and 1:25 wet climate scenarios are summarized in Table 3-20 for the MacLellan site.

Table 3-20 BL-WB Predicted Streamflow Results for MacLellan LAA

3.4.3 Project Water Balance Results

The results of the PROJ-WB for average and the 25-year wet and dry climate conditions are discussed in the following subsections for each of the Project components.

3.4.3.1 Open Pit

Flow components into the open pit include groundwater seepage, precipitation, surface runoff from prepared and natural areas, evaporation and dewatering. Figure 3-14 to Figure 3-16 present the average monthly groundwater inflow rate and flows from direct precipitation, contribution from natural ground and prepared ground under for climate average, 25-year dry and 25-year wet climate scenarios to the open pit. The total dewatering rates and losses due to evaporation are also presented. The total dewatering rate includes groundwater inflows and net precipitation.

Under the average case, monthly dewatering rates from the open pit ranges from 18 m^3/day to a maximum of 8,630 m^3/day. Under 25-year dry and 25-year wet climate scenarios the monthly dewatering rate from the open pit ranges from 13 m^3/day to a maximum of 8,535 m^3/day and from 24 m^3/day to a maximum of 9,350 m^3/day respectively. During spring freshet (April and May) 75% of the dewatering flows were directed to the TMF and 25% of the dewatering flows were directed to the collection pond. For the remaining months, all dewatering flows were directed to the collection pond. Groundwater inflow rates to the open pit ranges from 0 m^3/day to 8,288 m^3/day and accounts up to 96% of the pit dewatering flow.

Once mining is completed and dewatering is terminated, the open pit begins to fill from groundwater inflow, direct precipitation, surface water runoff, and water from collection pond and the TMF. Once water levels within the pit lake reach 330 m amsl, water from the pit lake will be directed to the Keewatin River via Kee3_B1. The model results demonstrate that it will take 30, 21 and 15 years to fill the open pit after the end of operation under 25-year dry, average and 25-year wet scenarios respectively (Figure 3-17). The annual discharge rate from the pit lake will range from 1,376 m^3/day to 8,108 m^3/day under average climatic conditions and is summarized in Table 3-21. The mean monthly pit lake over flow rates for 25-year dry and 25-year wet scenarios ranges from 1,217 m^3/day to 4,586 m^3/day and from 1,667 m^3/day to 12,759 m^3/day, respectively (Table 3-21).

Table 3-21 Open Pit Overflow Average Monthly Discharge Rates (m^3/day) Post-Closure – All Climate Scenarios

Parameter	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual Average
25-Year Dry	1,443	1,594	1,765	2,097	8,892	3,512	4,586	3,574	4,654	4,006	1,962	1,217	3,275
Average	1,784	2,182	2,431	2,764	12,643	6,219	8,108	6,411	7,246	5,510	2,576	1,376	4,938
25-Year Wet	2,380	2,847	3,188	3,646	17,599	9,794	12,759	10,157	10,671	7,497	3,388	1,667	7,133

3.4.3.2 Tailings Management Facility

The PROJ-WB was used to adjust the volume of water within storage in the TMF by balancing mill demand from the TMF with use of other contact water from the collection pond and from open pit. Figure 3-18 to Figure 3-20 presents the simulated TMF pond volumes which demonstrate surpluses above the 'dead' storage volume with all surplus water directed to the process plant to meet mill demand under average, 25-year dry and 25-year wet scenarios. The dead storage volume is the volume of water lost to the void spaces in the tailings. Potential storage is the maximum storage capacity of the TMF.

During active closure and post-closure, excess runoff from the TMF in the model is assumed to be directed to the open pit. Average monthly discharge rates from the TMF for average, 25-year dry and 25-wet climate scenarios are provided in Table 3-22.

Seepage through the TMF dams will be collected in the seepage collection ditches and ponds. During operation and closure, water from the TMF seepage collection ponds will be pumped back to the TMF and is already accounted for in the water balance. After closure, water from the seepage collection system will be discharged to the open pit.

Table 3-22 TMF Post-Closure Average Monthly Discharge Rates (m^3/day) – All Climate Scenarios

Parameter	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual Average
Average	91	281	379	508	4167	1238	1809	1269	1864	1532	432	0	1131
25-Year Dry	0	0	65	248	2709	188	443	169	859	948	194	0	485
25-Year Wet	356	541	675	851	6092	2625	3613	2722	3193	2303	747	81	1983

3.4.3.3 Mill and Processing Plant

The process water supply for the mill is provided from surplus water from the TMF reclaim pond and contact water from collection pond. Figure 3-21 to Figure 3-23 presents the volume of reclaim water supplied by each of the sources in comparison to the total reclaim demand for average, 25-year dry and 25-year wet climate scenarios.

The TMF is capable of meeting approximately 100% of the mill demand under average and 25-year wet climate scenarios, but under 25-year dry climate scenario water from the collection pond and other sources (Keewatin River) will be needed to meet the mill demand (Figure 3-22).

3.4.3.4 MRSA and Collection Pond

Runoff and toe seepage from the MRSAs are collected in a series of ditches and ultimately pumped to the collection pond, a portion may be pumped to the TSF. Similarly, open pit dewatering is directed to the collection pond. Figure 3-24 to Figure 3-26 presents the water sources that are collected in the collection pond for average, 25-year dry and 25-year wet climate scenarios.

Water from the pond is discharged to the Keewatin River after the discharge water quality requirements are met. Under average condition mean monthly discharge from the collection pond to Keewatin River ranges from 0 m^3/day to 14,200 m^3/day. Under 25-year dry and 25-year wet scenarios the discharge from the collection pond to Keewatin River ranges from 0 m^3/day to 12,700 m^3/day and from 100 m^3/day to 25,100 m^3/day respectively.

3.4.4 Results on Streamflow and Lake level

Flows and lake levels under baseline conditions (BL-WB) were used as the benchmark against which Project-related changes during the construction, operation, active closure and post-closure phases were assessed. The predictions of streamflow and lake levels for baseline conditions and during the life of Project are presented below.

3.4.4.1 Streamflow

Average monthly and mean annual flow changes during construction, operation, closure and post closure from the baseline conditions for those nodes effected by the Project are provided in Table 3-23 to Table 3-29, and graphically in Figure 3-27 to Figure 3-32.

Monthly and mean annual flow changes during construction, operation, active closure and post-closure from the baseline conditions for 25-year dry and 25-year wet climate scenarios are provided in Appendix C.

Keewatin River Downstream of the Mine Site (QM03)

Results for predicted streamflows under baseline and Project conditions for the average climate scenario are presented in Table 3-23. The changes in mean annual flow for each Project phase are:

- Construction: Mean annual flow is expected to increase by 0.022 m^3/s from baseline (7.908 m^3/s).
- Operation: Mean annual flow is expected to increase by 0.049 m^3/s from baseline (7.908 m^3/s).
- Active Closure: Mean annual flow is expected to decrease by 0.003 m^3/s from baseline (7.908 m^3/s).
- Post-Closure: Mean annual flow is expected to decrease by 0.001 m^3/s from baseline (7.908 m^3/s).

KEE3-B1 Unnamed tributary of the Keewatin River (QM04)

Results for predicted streamflows under baseline and Project conditions for the average climate scenario are presented in Table 3-24. The changes in mean annual flow for each Project phase are:

- Construction: Mean annual flow is expected to decrease by 0.023 m^3/s from baseline (0.035 m^3/s).
- Operation: Mean annual flow is expected to decrease by 0.022 m^3/s from baseline (0.035 m^3/s).
- Active Closure: Mean annual flow is expected to decrease by 0.022 m^3/s from baseline (0.035 m^3/s).
- Post-Closure: Mean annual flow is expected to increase by 0.027 m^3/s from baseline (0.035 m^3/s).

Keewatin River Downstream of the Mine Site (QM06)

Results for predicted streamflows under baseline and Project conditions for the average climate scenario are presented in Table 3-25. The changes in mean annual flow for each Project phase are:

- Construction: Mean annual change in flow is expected to decrease by 0.001 m^3/s from baseline (7.972 m^3/s).
- Operation: Mean annual change in flow is expected to increase by 0.026 m^3/s from baseline (7.972 m^3/s).
- Active Closure: Mean annual change in flow is expected to decrease by 0.025 m^3/s from baseline (7.972 m^3/s).
- Post-Closure: Mean annual change in flow is expected to increase by 0.025 m^3/s from baseline (7.972 m^3/s).

Minton Lake (QM07)

Results for predicted streamflows under baseline and Project conditions for the average climate scenario are presented in Table 3-26. The changes in mean annual flow for each Project phase are:

- Construction Mean annual change in flow is expected to decrease by 0.008 m^3/s from baseline (0.041 m^3/s).
- Operation: Mean annual change in flow is expected to decrease by 0.008 m^3/s from baseline (0.041 m^3/s).
- Active Closure: Mean annual change in flow is expected to decrease by 0.009 m^3/s from baseline (0.041 m^3/s).
- Post-Closure: Mean annual change in flow is expected to decrease by 0.009 m^3/s from baseline (0.041 m^3/s).

Cockeram River (QM11)

Results for predicted streamflows under baseline and Project conditions for the average climate scenario are presented in Table 3-27. The changes in mean annual flow for each Project phase are:

- Construction: Mean annual change in flow is expected to decrease by 0.007 m^3/s from baseline (1.116 m^3/s). The reduction in flow of Cockeram River at the inlet of Cockeram Lake is associated with the reduction in total drainage area that drains into the Minton Lake where the TMF is located, and the reduction on area that drains directly to Cockeram Lake.
- Operation: Mean annual change in flow is expected to decrease by 0.008 m^3/s from baseline (1.116 m^3/s).
- Active Closure: Mean annual change in flow is expected to decrease by 0.008 m^3/s from baseline (1.116 m^3/s).
- Post Closure: Mean annual change in flow is expected to decrease by 0.008 m^3/s from baseline (0.041 m^3/s).

Cockeram Lake (QM08)

Results for predicted streamflows under baseline and Project conditions for the average climate scenario are presented in Table 3-28. The changes in mean annual flow for each Project phase are:

- Construction: Mean annual change in flow is expected to decrease by 0.002 m^3/s from baseline (13.727 m^3/s).
- Operation: Mean annual change in flow is expected to decrease by 0.030 m^3/s from baseline (13.727 m^3/s).
- Active Closure: Mean annual change in flow is expected to decrease by 0.023 m^3/s from baseline (13.727 m^3/s).
- Post Closure: Mean annual change in flow is expected to increase by 0.028 m^3/s from baseline (13.727 m^3/s).

Details of the predicted monthly streamflow plots at hydrometric stations listed in Table 6-2 for baseline condition and during the project life are presented in Appendix D (Figure D-1 to Figure D-11).

3.4.4.2 Lake Level

Results for predicted lake level under baseline and Project conditions for the average climate scenario are presented in Table 2-21 to Table 2-21, 25-year dry and 25-yr wet climate scenarios can be found in Appendix C. The changes in mean annual lake level for all Project phases are:

Burge Lake

No results are provided for Burge Lake as it is upstream of any Project related effects.

Minton Lake

Results for predicted lake level under baseline and Project conditions for the average climate scenario are presented in Table 3-30. The changes in mean annual lake level for each Project phase are:

- Construction: Mean annual lake levels decrease 0.02 m from baseline. The reduction in flow at Minton Lake is associated with the reduction in total drainage area that drains into the Minton Lake where the TMF and MRSA are located.

- Operation, Active Closure and Post-closure: Mean annual lake levels decrease 0.03 m from the baseline. The reduction in flow at Minton Lake outflow is associated with the reduction in total drainage area that drains into the Minton Lake where the TMF and MRSA are located.

Cockeram Lake

Results for predicted lake level under baseline and Project conditions for the average climate scenario are presented in Table 3-31. The changes in mean annual lake level for each Project phase are:

- Construction, Operation, Active Closure, and Post-closure: Mean annual lake levels are predicted to have negligible change (<0.005 m) from baseline.

Predicted lake levels for the baseline conditions and during the Project life (construction, operation, active closure and post-closure) are also presented in Figure 3-33 to Figure 3-34 for Minton Lake, and Cockeram Lake, respectively.

Table 3-29 Predicted Lake Level for Existing and Project Conditions for Minton Lake - Average Climate Scenario

4.0 WATER QUALITY MODEL

4.1 GENERAL APPROACH

As described in Section 2.0, the WQM consists of the BL-WQM and the PROJ-WQM sub-models. Like the WB, the PROJ-WQM builds upon the inputs and assumptions defined in the BL-WQM. The two sub-models run concurrently so that Project impacted predictions can be compared to baseline predictions at each timestep in the model. Scenario modelling (Section 4.1.1) and the parameters of interest (POIs; Section 4.1.2) in both sub-models are consistent.

4.1.1 Scenario Modelling for the WQM

Water quality predictions are presented for two cases/scenarios: Expected Case and Upper Case (Table 1-1).

Table 4-1 Water Quality Model Scenarios Descriptions

Scenarios	Flow Condition	Load Condition
Expected Case	Monthly Average	Median water quality or median of last 20 weeks for source terms with conservative assumptions.
Upper Case	Monthly Average	95th percentile of all datasets or the 95th percentile of geochemical test work or tests samples based on geochemical samples classified as extreme. Source term development also includes conservative assumptions.

The Expected Case scenario incorporates mass loading conditions based on average inputs and assumptions commonly incorporated into load models to predict the anticipated water quality. The Upper Case scenario includes adjustments to inputs in the WQM. Specifically, the background concentrations are adjusted to the 95th percentile of observed values and the source terms are calculated using loading rates from geochemical tests conducted on materials that are considered “extreme” based on ABA data (i.e. not representative of average static testing results as discussed in Stantec (2017c, 2020d). Further to this, the scaling factors and groundwater flow assumptions incorporated into the Upper Case scenario reflect “possible” values that are considered highly conservative. Due to the high level of conservatism in the inputs and assumptions applied to the Upper Case scenario, it is recommended that these predictions are used for contingency planning only.

4.1.2 Parameters of Interest and Guidelines

The mass loadings to and from each model node were calculated for the parameters of interest (POI), these POIs are regulated by the guidelines listed in Table E-1 (Appendix E), regardless of exceedances.

- *Canadian Water Quality Guidelines* (CWQG) for the Protection of Freshwater Aquatic Life by Canadian Council of Ministers of the Environment (CCME 2019).
- *Manitoba Water Quality Standards Objectives and Guidelines* (MSOG) for Freshwater Aquatic Life by Manitoba Water Stewardship (MWS 2011).

- *Metal and Diamond Mining Effluent Regulations of the Fisheries Act* (MDMER 2018).

In addition to the POIs listed in the documents mentioned above, the supporting parameters such as general water chemistry were modelled. The POIs that are modelled are summarized in Appendix E (Table E-1).

TSS is not predicted because it is assumed that all discharge from the open pit will meet the MDMER limit of 15 mg/L. pH is not predicted for the reasons discussed in section 4.1.3.

The predicted concentrations of POIs at model nodes were compared against applicable water quality guidelines Appendix E (Table E-1). Predicted POIs that exceed long term guidelines in the receiving environment, or short term and/or MDMER guidelines in effluent from the mine. Guidelines that are dependent on pH, hardness, or temperature are calculated based on the average observed baseline hardness, temperature, pH values.

4.1.3 Potential Development of Acidity

At mine sites, acidic rock drainage (ARD) occurs due to exposure of sulphide and sulphate mined minerals to the atmosphere. The minerals in the newly exposed mined rock will subsequently react with the oxygen in the atmosphere and oxidize. The oxidation of iron bearing sulphidic material will produce acid; however, this acidity can be buffered by alkalinity released by the dissolution of carbonate and aluminosilicate (neutralizing) minerals, which are also often contained in mined rock. As sulphides are oxidized and neutralizing minerals dissolve, the overall amount of sulphide minerals and neutralizing minerals in the rock depletes. If the initial amount (based on molar equivalency) of acid generating minerals (sulphides) exceeds neutralizing minerals, once all of the neutralizing minerals are depleted in the mined rock, they will no longer be able to buffer acid from the sulphidic minerals and net acidic condition will develop. The acidic drainage will accelerate the rate of sulphide oxidation and increase the rate POIs are released to contact water (i.e. increase the loading rate). The time it takes for the neutralizing minerals to deplete (and acidic drainage to ensue) is called the “ARD lag time”.

The waste management plan for the site will outline strategies for mine rock placement that will reduce the potential for mine rock to develop locally acidic conditions as a result of sulphide oxidation. As described in Stantec (2017c, 2020d), approximately 28% of mine rock material at the MacLellan site is classified as potentially acid generating (PAG). The loadings rates incorporated into the WQM account for the possibility that PAG rock will release POIs to contact water under acidic conditions during post-closure (described in section 3.2.1.2) so that predictions remain conservative; however, a key assumption in the PROJ-WQM is that the seepage will maintain a neutral pH. One strategy to reduce the potential for PAG rock to develop acidic drainage is to intimately blend the PAG material with the non-PAG materials (72%) so that there is a continual source of neutralizing minerals.

With respect to the PAG tailings material contained in the TMF, the model assumes the tailings material will not generate ARD at closure because of mitigation and management strategies implemented.

4.2 BASELINE WATER QUALITY MODEL

The BL-WQM has been constructed to predict baseline water quality at the MacLellan site. It is built upon the assumptions and predictions calculated in the BL-WB and integrates natural background source terms (catchments and groundwater) into the flows and reservoirs of the BL-WB (Stantec 2020f). The BL-WQM simulates the baseline water quality conditions by identifying the sources, pathways and receivers (which form the basis of the baseline conceptual model described in Section 4.2.1) and identifying and incorporating inputs and assumptions specific to pre-mining conditions (Sections 4.2.2) into the model.

4.2.1 Baseline Water Quality Conceptual Model

The conceptual model for the BL-WQM (Figure 4-1) is largely dependent on the catchments delineated as part of the water balance in Map 3-2 and Map 4-1. Overall, the conceptual model for the Maclellan BL-WQM accounts for two distinct flow paths. The first flow path begins in Burge Lake to the north. Burge lake drains into the Keewatin River. The Keewatin River travels south and mixes with the Lynn River and ultimately discharges into Cockeram Lake. The second flow path begins in Minton Lake (located to the south of the Project), which discharges into Cockeram River and ultimately drains into Cockeram Lake.

The conceptual model for the BL-WQM consists of "cells" which correspond to model nodes in the BL-WB. There are two types of cells (source cells and mixing cells). Each model cell receives inflows from the catchment equivalent to the inflows, reservoirs and flow-through functions calculated in the BL-WB, while mass loading rate of inflows are added to cells within the WQM portion of the WBWQM. The advective mass flux out of all cells is determined as concentrations calculated in the cell multiplied by the outflow rate determined in the WB at the equivalent model node.

The source cells represent undeveloped areas and lakes that do not receive any upstream or outside loads (i.e. behave as model boundary conditions and/or inputs). Source cells have defined water quality and are represented in the conceptual model by smaller icons on Figure 4-1. Ultimately, the WQM transfers mass from source cells to mixing cells (representing reservoirs, ponds, lakes and river sections). Mixing cells are connected by links (representative of flow paths) to other downstream mixing cells. These cells can also receive loads from outside sources as direct loads. In the conceptual model (Figure 4-1), larger icons represent mixing cells.

The naming convention for each cell is the same as the model node; however, the symbol "_CT" is added to the end of the model node (e.g., "QF01_CT"). Model nodes names are based on the corresponding hydrometric/flow station (where one exists), described in Table 4-2; however, model nodes do not always correspond to water quality monitoring stations. At times, the corresponding water quality monitoring stations are within the catchments; however, for catchments without stations, the nearest water quality station is used to represent predicted water quality. The water quality predictions for the BL-WQM are validated against the water quality observed in the corresponding water quality monitoring station. The location of the water quality stations are presented in Map 3-2 and Map 4-1 and the relationship between each catchment node and water quality monitoring station is described in Table 4-2.

Table 4-2 Relationship Between Assessment Model Node and Hydrometric/Water Quality Stations

WQM Node/cell (CT)	Hydrometric Station	Water Quality Station	Notes
Kee3_Pay1_CT	None	AQM31	AQM31 is significantly upstream in Payne Lake (KEE3_PAY2) while the model node is located at the foot of the tributary.
QM02_CT	QM02	AQM4	AQM4 is significantly upstream of the model node. KEE3_PAY1 discharges into this model node.
QM03_CT	QMO3	AQM7	Includes discharge from the collection pond during operations (described in the PROJ-WB)
KEE3_B1_CT	QMO4	QM18	Includes discharge from the open pit overflow at closure. QMO4 not used to calculate flow in the WBWQM. AQM18 is located in a lake located in the center of the catchment.
QM06_CT	QMO6	AQM8	Includes discharge from KEE3B1 catchment
QM05_CT	QM06+QM05	AQM29	QM05 is within Lynn River, prior to Lynn River and Keewatin River confluence. QMO6 is on Keewatin River prior to Lynn River and Keewatin River confluence AQM29 is downstream of confluence between rivers.
QM08_CT	QM08	AQM11	Receives inflows from Keewater River and Cockeram River Water quality at lake outlet
QM10_CT	QM11	AQM10	Combines two sub-water sheds
Minton Lake_CT	QMO7	AQ16	Minton Lake outlet includes catchment from the Lake (Min4_CT) and Min5_CT. AQM22 water quality exists for Min5_CT catchment but is not used in the model.

4.2.2 Baseline Source Terms and Assumptions

The source terms incorporated into the BL-WQM are based on observed baseline water quality. The water quality is applied to each source cell or groundwater mass loading input term. In both cases, the load is calculated by multiplying a defined water quality by the calculated flow in the BL-WB. The observed water quality that is used to calculate concentrations in each source cell is provided in Appendix E

4.2.2.1 Baseline Surface Water Quality Source Terms

The water quality applied to each source cells within the BL-WQM was obtained from datasets collected from surface water quality monitoring stations located at or near each equivalent cell (Appendix E, Tables E-3-1 and E-3-2).

All water quality inputs were prepared using following water quality dataset processing steps:

Step 1: Detection limits

Concentrations of some elements were reported below detection limits. For measured concentrations below detection limit, the full detection limit was used for the model inputs.

Step 2: Grouping and checking seasonal data

Surface water concentrations were grouped by season for selected stations as follows:

- Spring: May and June
- Summer: July and August
- Fall: September and October
- Winter: November, December, January February, March and April

Observed POI concentrations that exceeded or were approaching water quality guidelines (Appendix E), were checked for outliers. Outliers were removed if it was suspected to be caused by sampling/analytical error prior calculation of statistics.

Step 3: Calculation and adjustment of statistics

For surface water inputs, average and 95th percentiles were calculated for each station and season as defined in step 2.

For stations where sampling was not consistently conducted (e.g., steam frozen to the bottom), statistics from the preceding season were used. The water quality predictions were also reviewed to ensure that total concentration (particulate and dissolved concentrations) was greater than dissolved concentrations incorporated into the source term. The dissolved concentration was greater than the total concentrations, the following adjustments were made to the source term:

- If dissolved fraction> total, then dissolved fraction = total fraction
- If dissolved Cr VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved Cr
- If free cyanide > WAD cyanide, then free cyanide = WAD cyanide
- If WAD cyanide > total cyanide, then WAD cyanide = total cyanide
- If nitrite (as N) > nitrate + nitrite (as N), then Nitrite (as N) = nitrate + nitrite (as N)

4.2.2.2 Groundwater Quality Source Terms

Baseline groundwater inflows were considered for only for cells/nodes were groundwater discharges were changed by the project according to Stantec 2020b). Concentrations applied to these groundwater inflows were based on the observed groundwater quality presented in the Stantec (2020e) and summaries are presented in Appendix E (Tables E-4-1 and E-4-2). Groundwater was filtered prior to sampling and only dissolved concentrations were presented for the trace metal POIs. Average and 95th percentile groundwater concentrations were calculated for each monitoring well by following the water quality dataset processing steps outlined in Section 4.2.2.1 with the notable difference that dissolved concentrations were assumed to be equivalent to the total concentrations to account for the natural filtration as water moves through geological units.

The averages/95th percentiles were grouped to represent various units/source, including:

- Background bedrock
- Background overburden

For each group, the geomean and $\log_{10}$ of 95th percentile concentrations were calculated, and a geometrical distribution was assumed. This approach was applied to the groundwater source term calculation due to the heterogeneity in the observed groundwater concentrations. The groundwater mass inflows to Minton Lake was based off an assumption that 20% of the overall inflows comes from the overburden unit and 80% bedrock of the inflows comes from the bedrock unit. Therefore, 20% of the water quality applied to this inflow is equivalent to overburden concentrations and 80% of the water quality is equivalent to bedrock concentrations.

4.2.2.3 Historic Mine Components Input Assumption

The Project site includes two historic mine components, an historic rock storage area (RSA) and underground workings from the former mine. The RSA is not adjacent to an existing river or water body and thus is not considered in the BL-WQM; however, any runoff and/or toe seepage that runs over and/or through the pile is captured in the BL-WQM because the observed catchment water quality is used as source term inputs to the BL-WQM. The existing underground workings are not currently discharging to surface water.

4.2.3 BL-WQM Validation

WBWQM validation is an important step in water quality modelling. Validation is the comparison of the calibrated model results to observed values. Predicted baseline concentrations at model nodes were compared to observed concentrations using relative percent of difference (RPD) as RPD = $(C_{model}-C_{observed})/C_{observed}\times100\%$. For the Expected Case, modelled concentrations were compared to average observed seasonal values (Appendix E, Table E-5-1 and Table E-5-7). The positive RPD's indicate the predicted concentrations are greater than observed concentrations (i.e. the model overpredicts concentration). Concentrations that are overpredicted are considered conservative, particularly when evaluating future project effects. Negative RPD's indicate the predicted concentrations are less than the observed concentrations (i.e. the model underpredicts concentrations).

A parameter was considered validated if the RPD was overpredicted and within 100% of the observed values or underpredicted and within 50% of the observed value in the Expected Case. Fifty percent was considered a satisfactory RPD for underpredictions for the following reasons:

- The degree of uncertainty associated with applying the average concentration of spot measurements (reflective of a single moment in time) and the uncertainty associated with the overall sample variability can be large (order of magnitude error is not uncommon for water quality datasets for some parameters). This variability is captured in the Upper Case model and is considered during model validation.
- Error associated with laboratory analysis is typically 20%.
- Error in field measurements can be as high as 25%.
- The concentrations of many parameters such as nitrite, chromium, cadmium, selenium, and silver were at or below the instrumental detection limit which could easily result in analytical errors +/-100%.

With the exception of modelling node QM05 (discussed below), in general, the comparison of predictions and observations show that the baseline model provides a solid basis for the further addition of project components (Appendix E, Table E-5-1 and Table E-5-7).

4.2.3.1 Model Validation and Calibration at QM05

Validation of the BL-WQM showed that parameters at AQM29 (model node QM05) were generally overpredicted (i.e., predicted greater than observed) due to inflows from the Lynn River (defined by water quality observed at water quality monitoring station AQM28). Further calibration of the AQM28 source term indicated that the concentration of some POIs in the Lynn River catchment was 60% greater than is calculated in the mass balance and that reducing concentrations in the Lynn River by 60% generally resulted in a reasonable model validation. However, a 60% loading reduction to concentrations from the Lynn River could not be applied universally to all parameters because this resulted in significant underprediction (i.e. predicted less than observed) of POIs.

To evaluate the overpredicted concentrations at QM05 in additional detail, the concentrations at the downgradient model node (QM08) were also considered in the validation process. If a parameter was found to be overpredicted at model node QM05 and QM08 in the Upper Case scenario, this was considered reasonable evidence of an attenuation mechanism and a 60% reduction to load was applied to the respective parameter in the Lynn River (AQM28). However, if the parameter was overpredicted at model node QM05 yet reasonably predicted (i.e. not overpredicted or underpredicted) at model node QM08, this indicated a likely combination of incomplete mixing, sampling error, overall variability in flow and/or observed concentrations, and the POI was not adjusted.

Parameters had an acceptable calibration (identified through visual inspection) were identified as reasonable and no modification to the source term was conducted. If the calibration indicated that parameters at model node QM05 were overpredicted but reasonably predicted at QM08, no adjustment to the source term was conducted but screening in of this parameter at QMO5 should only be conducted if there is significant deviation from baseline concentrations. If the parameter was overpredicted at model node QM05 and QM08, then a 60% reduction to load was applied to the following parameters: nitrite, dissolved cadmium, total cadmium, dissolved chromium, dissolved cobalt, total cobalt, total lead, and total manganese. A reduction of 20% was applied to total aluminum and total iron.

4.3 PROJECT WATER QUALITY MODEL

To model water quality effects, the PROJ-WQM is built upon operational flow rates and reservoirs volumes calculated in PROJ-WB. The PROJ-WQM includes the Project site and loadings related to mine operations, as described in the conceptual models (Section 4.3.1) and is based upon source terms and assumptions (Section 4.3.2) specific to each source (i.e. mine component). This information is used to predict impacts to discharge water quality and impacts to the receiving environment (Section 4.4).

4.3.1 Water Quality Model Conceptual Model

The conceptual model for the PROJ-WQM differs from the BL-WQM in that it includes the Project components. As such, presentation of the conceptual models described in this section follow the same approach outlined for the BL-WQM conceptual model in Section 4.1, with two notable differences. In addition to the blue icons representing nodes unimpacted by mine water, the PROJ-WQM conceptual models also include grey icons and orange icons. The grey icons signify mine rock loading source cells, and the orange cells indicate mixing cells that receive contact water from the Project.

The conceptual models outlined for each phase: construction, operation, closure/post-closure for the MacLellan Site are presented in Figure 4-2 to Figure 4-5, respectively. The major mine components include the MRSA, the TMF, the collection pond and the open pit. These mine components are the primary loading sources in the model. The domain within the PROJ-WQM outside of the PDA remains largely unchanged from baseline conditions, with the exception that mixing cells located downgradient of the PDA receive contact water (shown by orange icons). Furthermore, groundwater from the mine site is assumed to discharge into cells located outside of the PDA, as shown in Figure 4-3 and Figure 4-5.

4.3.2 Project WQM Inputs

This section discusses mass loading input specific to the PROJ-WQM. Inputs and assumptions that impact flow are discussed as part of the BL-WB and inputs common to both the BL-WQM and PROJ-WQM are discussed in Section 3.2.

4.3.2.1 Mine Components Assumptions and Source Terms

The assumptions and the source terms associated with each source (i.e. mine component) in the PRO-WQM are outlined below. At times, the methodology used to develop a source term is applicable to multiple mine components. If this is the case, the development of the source term is presented followed by a discussion of the mine component specific assumptions. For mine components that have source terms that are unique to that mine component, the source terms are discussed together with assumptions.

Source Terms for Loads Associated with Flow Rates

As with the baseline source term, the loading rate to each mixing cell in the PROJ-WQM from upgradient cells can be calculated by multiplying the observed water quality by the calculated flow rate (defined in the PROJ-WB). For source terms applied to a source cell this calculation is used to determine outflows from the cells and inflows to the subsequent mixing cell. This approach is used to calculate loads associated with:

- Natural runoff (TMF, open pit, collection pond, catchments potentially affected by the Project).
- Groundwater seepage / inflows to the open pit.

Mine Rock Source Terms

Mine rock includes mine rock in the MRSA, ore, TMF embankments, as well as the rock walls and rubble on the benches of the open pit. It does not include tailings material. Mine rock source terms include the loads from rock rubble pit and pit walls as a result of weathering and 2) of nitrogen species leached from undetonated explosives.

Source Terms for Exposed Mine material Loadings

The source term for the elemental leaching rates (R) of exposed mass are based on average rates estimated from representative sources (generally field bins tests) and by applying scaling factors (SF) to convert the loading rates of the geochemical tests to loading rates that would be expected from field components. Leaching rates are calculated using Equation 4-1:

$R = M \times R_{FB} \times SF_{SURFACE\ AREA} \times SF_{CONTACT} \times SF_{POSTCLOSURE}$ *Equation 4-1*

Where:

- M = kilotonnes rock/ore mass of rock exposed
- R_{BF} = Loading rate of the geochemical test, (typically the rate observed in the field bin).
- $SF_{SURFACE\ AREA}$ = scaling factor for rock surface area.
- $SF_{CONTACT}$ = contact factor accounting for a reduction in solute leaching due to hydraulic isolation, which is limited in field bin tests.
- $SF_{POSTLOSURE}$ = reduction of element leaching rates in post-closure due placement of covers.

A summary of all scaling factors applied to each mine component where mined material is a source term is provided in Table 4-5.

The loading rates incorporated into the source term are equivalent to loading rates calculated from field bin leachates (Appendix E, Table E-6). All loading rates were obtained from neutral drainage, as none of the geochemical tests have developed acidic leachate. Therefore, the source term for acidic drainage is not described in this section. Field bin loading rates were used instead of the humidity cell loadings rates for the reason that weathering in field bins occurs under site conditions and thus water quality from this source does not require adjustments for temperature. Initially, leaching rates for freshly mined rock are elevated (with respect to longer term loading rates) as soluble minerals are flushed from the rock. However, loading rate often tend to decrease over time in neutral leachate. So that operational loading rates remain conservative, the loading rates during operations are based on the average observed loading rates in the field bins while the closure loading rates are only based on the third year of collected data.

The rate at which materials leach POIs is related to the surface area of the material because there are less exposed mineral grains on smaller surface areas (i.e. coarser fragments). Rock in field bins were crushed to - ¼" and therefore loading rates are scaled to account for the difference between this surface area and the surface area expected for blasted rock, which is coarser and smaller. The surface area scaling factor is based on the particle site distributions (PSD) assuming spherical particles. Mine rock PSD were taken form Diavik mine studies (Bailey et al. 2012) and resulted in 1.94 m^2/kg. The average weighted surface areas for crushed mine rock are assumed to be 39.6 m^2/kg and 25.3 m^2/kg for Expected and Upper Case, respectively.

A contact scaling factor is applied to the calculation to account for the amount of rock that will be exposed to infiltrating water. A contact scaling factor of 0.3 and 0.65 is selected for Expected and sensitivity cases respectively. These numbers are based on a literature review (Kempton 2012).

Finally, an additional scaling factor (0.8) is applied to the source terms during post closure to account for the reduction in infiltration through the rock as a result of cover placement (MRSA and embankments only). During operation and closure the post-closure scaling factor for all mine components is equal to 1 conservatively assuming no reduction in the leaching rate.

Source Terms for N Species

The blasting of mine rock will release nitrite, nitrate and ammonia, which subsequently will be rinsed from the rock and contribute loads to contact water. The mass rate of lost (non-exploded) nitrogen (R_N, g/yr) was calculated using *Equation 4-2*:

$$R_N = MR \times PF \times F_N \times L_N \times FR_N \qquad \textit{Equation 4-2}$$

where,

> MR = total mining rate of ore + mine rock t/yr, (Appendix E, Table E-7) - PF = 300 g/t, Powder Factor based on the Mine Plan
>
> F_N = 0.333, fraction of nitrogen in the explosive based on 1/3 of nitrogen in the explosive (Bailey et al. 2012) dimensionless
>
> L_N = 0.002 and 0.01 for Expected and Upper Cases respectively based on 0.2% nitrogen of total nitrogen used loss from Ferguson and Leask 1988 and 1% as maximum observed in dry open pit mines in Table A-4 from Golder (2008)
>
> FR_N = 0.1 (10%), fraction of nitrogen released from rock and ore while in the open pit, prior material transfer to storage areas, assuming that another 90% will be leached in storage areas based on Golder (2007).

The release of nitrogen species was assumed to be instant and the leached nitrogen was speciated as follows based on recommendations from Ferguson and Leask (1988):

- for the Expected Case: N-NH3 - 11%, N-NO3 - 87%, N-NO2 – 2%
- for the Upper Case: N-NH3 - 4%, N-NO3 - 95%, N-NO2 – 1%.

Table 4-3 Scaling Factors Applied to Mined Rock Source Terms

Component	M	$R_{Operations}$	$R_{UClosure}$	SF SURFACE AREA	SF CONTACT	SF POSTCLOSURE

Notes: 1 FLB indicates field bin loading rate applied to calculation AVG indicates average loading rate over the time period indicates
Expected indicates Expected Case and Upper indicates Upper Case.
All loading rates are provided in Appendix E; Table E6

PAG Rock Loading Rates

Static test information suggests that 28% of the mine rock will be PAG which is not expected to generate net acidic conditions during operations (Stantec 2017c, 2020e). As described in Section 4.1.3, waste management practice will be developed to reduce the amount of acid generated within the mine rock to the extent possible. None the less, so that estimates remain conservative, an assumption in the PROJ-WQM is that 28% of the rock (equivalent to the % of PAG rock in the ABA static database) will release loadings to the environment at elevated rates during post-closure.

There is no representative acidic leachate water quality for the rock or ore. Therefore, the PAG loadings rates were based on the 95th percentile concentrations observed in monitoring well MW-11 (Appendix E, Tables E-4-1 and E-4-2) located downstream of historical mine rock. This water quality was selected as it is the worst-case water quality currently observed on the site or in geochemical testing leachate. The concentrations from well MW-11 were back calculated in the model and applied as loadings rates directly (i.e. there were not scaled in the model). Back-calculation in the model was conducted by assuming that 100% of the MRSA was PAG rock and calibrating a loading rate scaling adjustment factor in the PROJ-WQM so that predicted sulphate concentrations matched observed sulphate concentrations.

MRSA Assumptions

The primary source term from loadings released from the MRSA is mine rock. The MRSA is located downgradient of the TMF and the pit. The leaching rates from mine rock storage areas (MRSA _CT) were calculated using Equations 4-1 and 4-2. The leaching rates were dependent on the mass of the MRSA (Appendix E, Table E-7).

The calculated total leaching rate ($R_+ R_N$) released to porewater stored in the MRSA cell is used to determine the concentration inside the stockpile MRSA pore water at each time step, while a smaller amount (1%) was released to the runoff component of flow. When mine rock is fully wetted (assumed to be immediate in the model), the volume of infiltrating water equals seepage from the MRSA. As described in the PROJ-WB, porewater discharges from the MRSA model node (which is a mixing cell) as both toe seepage (captured by the ditches) and bed seepage (which recharges the underlying aquifer). Mass is divided proportionally according to flow (described in the Section 3.0).

Runoff overtop of the MRSA is captured by the ditches and directed to the collection pond. During closure, a key assumption is that the MRSA will be covered, and the overland runoff water will not interact with the underlying mine rock. Once a cover is placed on the MRSA, the source term for runoff water is calculated based on the total expected runoff rate and the natural water quality of the catchment (AQM18).

Ore Stockpile Assumptions

The primary source term for the ore pile loading rate is mine rock. The size of the ore pile and ore through-put rate is presented in Appendix E (Table E-7). At closure it is assumed that all remaining ore in the stockpiles will be milled and the area will be reclaimed.

Embankments Assumptions

The primary source term for loads attributed to the TMF embankment is mine rock. It was assumed that all water infiltrates through the embankments and is captured by seepage collection ditches and either returned the TMF (operations) or directed to the open pit (closure).

Overburden Stockpile Assumptions

The source term used to calculate loads to the collection pond from the overburden storage area is based on natural runoff using the catchment water quality (AQM018). It is assumed that overburden is used for reclamation during closure and is depleted by the end of closure.

Open Pit Source Terms and Assumptions

During operations, mine water will be collected in sumps at the bottom of the open pit and redirected to a collection pond. During construction and operations, the open pit will be dewatered and there will be no direct discharges to the environment. During closure, the open pit will begin to flood. Once the open pit is flooded (post-closure), the excess water within the pit will discharge through the overflow spillway to a tributary of the Keewatin (KEE3-B1).

The direct loads (i.e. not including inflows from upgradient sources) to the open pit include mass inflows from groundwater, local/disturbed runoff and direct loadings from exposed material.

The groundwater model (Stantec 2020b) predicted that approximately 80% of water will originate from bedrock and the remaining 20% from overburden. Therefore, the groundwater source term described in the BL-WQM (4.2.2.2) is also used to calculate loadings related to groundwater inflows to the pit. The groundwater source term assumes that to 80% of the loads are attributed to bedrock inflows and 20% are attributed to overburden inflows.

The mine rock source term is used to calculate loadings to the open pit from rubble on the benches and the rock walls. Loading calculations conservatively assumed that the exposed rock is equivalent to 5% of the total mass of the MRSA. Further, it was assumed that as the pit expanded, the amount of exposed mass in the pit expanded proportionally to the MRSA and as the pit flooded during closure, the amount of exposed rock decreases proportionally as well.

During closure, the PROJ-WQM directs loads associated with runoff and toe seepage from the MRSA (through the collection pond) and TSF to the open pit lake. The open pit also receives some base seepage from the MRSA, as described in the groundwater modelling report (Stantec 2020b). At closure, an assumption in the model is that the pit lake stratifies, meaning that the upper portion of the pit lake does not mix with the lower portion of the lake. The loads from the collection pond and TMF are assumed to discharge to the bottom of the pit lake. However, because the only outflow to the pit lake is through the overflow spillway, the lower portion of the pit lake does mix with the upper portion until it reaches 85% of the total open pit storage capacity. A removal function is also applied to the surface water in the open pit to approximate sorption and settling of arsenic, cadmium and copper at a rate of 0.26, 1, 0.46 1 per year, respectively. Mass removal is only assumed to occur between May and October. Annual removal fractions were based on estimates from 15 years of Zone 2 pit lake monitoring at the Colomac mine site (Stantec

2017e). The sorption/settling rates incorporated into the upper portion of the open pit are consistent with the assumptions incorporated into the Gordon PROJ-WQM and considered reasonable because the upper part of the historic pit lakes at the Gordon site have better water quality than the pit lake at depth (Stantec 2017c).

TMF Source Terms and Assumptions

During operation, the TMF pond will receive mass loadings from the following sources:

- Discharge from process plant.
- Spring freshet from the open pit (load from a mixing cell).
- Leaching of elements from tailings beaches exposed to the atmosphere.
- Water from TMF seepage collection system pumped back to the TMF reclaim pond (operations).

Two first inputs are described above, while two last inputs are described below:

Leaching of Elements from Tailings Beaches

Element leaching rates from exposed tailings ($R_{TAILINGS}$) are calculated using *Equation 4-3*.

$$R_{TAILINGS} = R_{HC} \times r \times A_{BEACHES} \times D_{BEACHES} \times SF_{O2} \times SF_{T} \qquad \textit{Equation 4-3}$$

R_{HC} - mean humidity cell loading rates.

r - tailings density (2800 kg/m^3).

$A_{BEACHES}$ - the area of TMF beaches (m^2) based on assumptions on the WB.

$D_{BEACHES}$ - the depth of active oxidation in exposed tailings

SF_{O2} - oxygen scaling factor accounting in differences between fully oxygenated humidity cells and decline in oxygen concentrations in pores with depth

SF_T - temperature scaling factor reflecting differences in oxidation rates between laboratory (20°C) and field temperatures

The mean (Expected Case) and 95th percentiles (Upper Case) leaching rates from tailings humidity cells are used to calculate the source term of the tailings beach (Appendix E; Table E-6). The rates calculated from the humidity cells during the first month of leachate analysis are applied in the model during the operation and closure periods, while values calculated from the leachate collected during the last month of analysis are used to calculate the beach source term during the post-closure period.

The tailing beach areas are calculated based on the total area of the tailings (wet and dry beach area) so that assumptions remain conservative. The depth of oxidation in the beaches is estimated from 1D oxygen diffusion model (Appendix F). The 1D modelled estimated oxidation depth was 0.5 m during the operation and closure and 0.2 m in post-closure, after a soil and vegetated cover placed over exposed tailings. The results from the 1D modelling are also used to calculate the oxidation scaling factor (SFo2), which accounts for differences between fully oxygenated humidity cells and decline in oxygen concentrations in pores with depth. The SFo2 is 0.3 for operations and 0.253 during post-closure. The temperature scaling factor (SFT) is applied to the source term to account for the differences in oxidation rates between laboratory (20°C) and field temperatures. This source term is based on the Arrhenius Equation, with rates that are based on average monthly temperature inputs shown in Appendix E (Table C-8).

Tailings Management Facility Seepage Water Quality

The PROJ-WQM is structured so that the tailings pond and the tailings pore water are different mixing cells. The tailings pond cell recharges tailings pore water cell at rate equivalent to seepage from the TMF (toe seepage + bed seepage). Toe seepage is assumed to be captured by ditches and diverted to the collection pond while the bed seepage recharges the underlying aquifer. By modelling the tailings pore water as a separate cell, the PROJ-WQM was able to account for mass released to the tailings pond water that may not be observed in geochemical tests (such as process water). However, subaqueous column experiments have demonstrated that mass can also be released through dissolution to the pore water. This addition of mass is not captured using the mixing cell approach. Therefore, the information gathered from the subaqueous columns was incorporated into the predictions as well. The pore water quality was set equal to greater of the tailings pore water calculated in the mixing cell and the mean concentrations observed in subaqueous columns CND2P and CND7 (Appendix E, Table E-6). For the subaqueous column inputs, the average of mean values from the first month were used during the operation, while averaged concentrations form the last month were applied for the closure and post-closure and periods.

Tailings Pond Removal Rate

Mass is removed in the tailings pond due to mineral precipitation, sorption/settling, and degradation of cyanide. Mineral precipitation and settling is not considered in the model; however, cyanide degradation was incorporated into the predictions. A removal rate (0.018 1/day) was applied to cyanide concentrations. This rate is based on the results of aging tests (R_{AGEING}), which were conducted under UV light without aeration for 56 days provides the results from the aging tests (Appendix E, Table E-6). These laboratory derived rates were scaled to the field rates using *Equation 4-4*.

$$R_{DEGRADATION} = R_{AGEING} \times SF_T \times SF_{LIGHT} \times SF_{AERATION} \quad \textit{Equation 4-4}$$

R_{AGEING} = rates derived from laboratory tests

SF_T = temperature scaling factor

SF_{LIGHT} = scaling factor reducing rate due to daylight

$SF_{AERATION}$ = scaling factor accounting for aeration in the TMF pond

The temperature scaling factor (S_{FT}) is applied to the source term to account for differences in rates between laboratory (20°C) and field temperatures based on temperatures shown in Appendix E (Table E-8). The light scaling factor (SF_{LIGHT}) is set equal to 0.5. It is applied to the source term to account for the fact that only 12hr of day light are expected on average in the field compared to the 24 in the laboratory. Finally, the aeration scaling factor ($SF_{AERATION}$) was set to 1.4. This factor accounts for aeration in the TMF pond from wave action resulting in faster decomposition of and volatilization of cyanide based on Simovic (1984).

Degradation of cyanide species results in formation of ammonia. Rate of ammonia addition in TMF pond from this process was calculated using Equation 4-4 assuming the same inputs and scaling factors.

Mill Source Terms and Assumptions

Water directed to the mill to meet processing requirements is typically reclaimed from the TMF pond; however, the PROJ-WQM, also assumes that water can be reclaimed from the collection pond should it be required. It is subsequently returned to the pond as slurry water. Elements/species are released from ore and/or added into the process solution during the milling and cyanidation process. These solutions are subjected to cyanide detoxification resulting in removal of many elements from the solution prior discharge to TMF. The concentrations in solutions after metallurgical testing and cyanide detoxification were used in *Equation 4-5* to calculate mass rate (R_{MILL}) added to the cell representing mill (Mill_CT).

$$R_{MILL} = Q_{SLURRY} \times C_{DETOX} \qquad \textit{Equation 4-5}$$

where,

Q_{SLURRY} = volume water discharged with tailings slurry (refer to Section 5.1.6)

C_{DETOX} = concentrations after cyanide detoxification. Average values were used for the Expected Case and 95 percentiles for sensitivity case (refer to day 0 for ageing tests in Appendix E (Table E-6).

Another important source of POIs to the water discharged to the TMF as slurry includes the mass already contained in water reclaimed from the TMF / collection pond. The source term for the reclaimed mass is equal to the concentration in the pond multiplied by the rate of recycled water pumped from the TMF (refer to Section 5.1.6). During processing, most trace metal cations tend to precipitate out of solutionl however some minerals accumulate. Oxyanions are mobile at neutral pH and tend to be the parameters that accumulate in TMF pond water. To account for this mass loss, the recirculation source term only maintains mass loads for bromide, chloride, fluoride, N-species, sulphate, cyanide species, arsenic, antimony, molybdenum, selenium, sodium and vanadium.

Collection Ditches Assumptions

There are no direct loads and/or source terms for the collection ditches. The assumptions for the collection ditches are flow-based and described in the WB.

Collection Pond Assumptions

There are no direct loads and/or source terms for the collection ponds. The assumptions for the collection pond are flow-based and described in the WB.

Groundwater Seepage Assumptions

The PROJ-WQM assumes that bed seepage from the TSF and the MRSA ultimately discharges into the receiving environment. The groundwater seepage rates are based on the groundwater particle tracking information described in the Stantec (2020b). The amount of seepage that discharges into each receiving node is assumed to be equivalent to the total amount that will discharge into the receiver 300 years following mine closure. This approach is considered conservative because the seepage rate at the last time step in the WBWQM (Year 128) is generally less than the 300-year seepage discharge rate. The particle tracking results indicate that is can take thousands of years for the plume to reach the receiver.

The amount of time it takes for seepage from the MRSA/TMF to reach the receiver is not modelled gradually in the PROJ-WQM. The model assumes that groundwater discharges at the mean predicted particle tracking travel time for the Expected Case and the minimum predicted travel time for the Upper Case scenario.

All groundwater mass flows are attenuated by 10% to account for potential dispersion, diffusion, retardation, and attenuation along the flow path. This amount of attenuation is well within the uncertainty in the PROJ-WQM and likely to be significantly higher within the aquifer, depending on the parameter. Further, bed seepage from the MRSA and TMF that discharges into catchment KEE3-B1 (tributary of the Keewatin) constitute the majority of flow in that tributary, as the bed seepage discharges slightly downgradient of the collection ditches. During the winter, bed seepage from the facilities to KEE3-B1 is assumed to freeze; however, it is also assumed to melt in April. This assumption is conservative for the reason that in April the stream flows are still low as snowmelt does not occur until later in the year. Therefore, adding seepage during this period of time results in minimal dilution of the bed seepage water with non-contact water.

Sewage Treatment Effluent

The collected sewage from the Gordon site buildings will be conveyed by gravity through buried PVC piping to two septic tanks at the truck shop and administration building. It will then be trucked to MacLellan for processing at the MacLellan sewage treatment plant. The sewage from the MacLellan site buildings will be collected via a network of buried PVC piping and manholes and conveyed by gravity to a 60 m3/d sewage treatment plant located at the MacLellan site. The effluent from the plant is not included in the model at this stage.

4.3.2.2 Solubility Constraints

The PROJ-WQM conservatively passes mass through the cells. The one exception includes solubility limits (cap) concentrations placed on aluminum, copper and iron predictions (i.e. the solubility caps do not allow predicted concentrations to increase above the cap concentrations). These caps are included in the model (applied to all model nodes) because the concentrations of these elements are often limited by thermodynamic constraints (i.e. once concentration reaches a certain value, minerals will precipitate out of the water column). In oxic neutral drainage, iron will precipitate out of solution as iron oxyhydroxides. Likewise, in neutral drainage, aluminum will precipitate out of solution is aluminum hydroxides or gibbsite. Copper commonly precipitates out of solution as tenorite or copper carbonates such as malachite.

The solubility, and therefore solubility caps of these minerals is highly dependent on reactant concentrations, pH and redox state. To determine the solubility cap for site specific conditions, the observed concentrations of these parameters were evaluated (presented in Table 4-6). Based on this evaluation, the solubility cap for dissolved aluminum was determined to be 0.2 mg/L. Higher surface water total aluminum concentrations were observed however this was assumed to represent suspended particulate matter and thus would likely be filtered through the ground. This solubility cap corresponded to concentrations generally observed in groundwater and in the Lynn River, which is a river highly influenced by upstream tailings deposits.

Iron solubility is highly dependent on redox state; therefore, the solubility cap was set to 0.7 mg/l (which is consistent with AQM28 and AWM16 and higher than in groundwater from the historical MRSA monitoring point (MW-11). Higher iron concentrations were observed in overburden and bedrock; however, iron is mobile in reducing conditions and concentrations tend to be elevated as a result. Once iron discharges to oxic surface water receivers it will precipitate out of solution. Groundwater concentrations are not considered reflective of the conditions associated with the surface water assessment nodes.

The copper concentration cap is set to 0.03 mg/l. This cap is higher than the MRSA concentration and the mean overburden concentration (not shown) and it is consistent with the AQM28 water quality which is assumed to be saturated with copper minerals.

Table 4-4 Range in Seasonal P95 Concentration at Key Model Nodes Used to Develop Solubility Caps

Water Quality Monitoring Station	Aluminum Concentrations (mg/L)		Iron Concentrations (mg/L)		Copper Concentrations (mg/L)	
	Dissolved	Total	Dissolved	Total	Dissolved	Total

4.1 WATER QUALITY PREDICTIONS

The WQM prediction statistics (max, min, mean for each month of each phase of the project) of the Expected Case and Upper Case for point source discharge water quality and receiving environment water quality, are summarized as tables in Appendix G. Likewise, plots of POIs modelled in the PROJ-WQM for the Expected and Upper Cases are presented in Appendix H. The overall general trends observed at each model node and the predicted exceedances of relevant water quality guidelines / benchmarks are discussed in this section. The predicted water qualities of bed seepage (i.e. not captured in seepage collection ditches) from the TMF and the MRSA are presented in Appendix I for the Expected Case and Upper Case respectively; however, the seepage water quality is not discussed directly in this report as groundwater discharge to the receiving environment is assumed to be diffuse and subject to considerable dispersion and attenuation.

4.1.1 Point Source Mine Discharges

In the PROJ-WQM, point source discharges of contact water from the mine to the immediate downgradient receptors include:

- Discharge from the collection pond to the Keewatin River (model node QM03) during operations.
- Overflow from the open pit directly into a tributary of the Keewatin River (KEE3-B1) during post closure (once the open pit is flooded).

4.1.1.1 Collection Pond

As outlined in the conceptual model, the collection pond model node discharges to modelling node/cell QM03 during construction and operations. The collection pond collects dewatering water from the MRSA (east section), open pit, any overflow from the TMF, as well as site runoff. It also acts as a source of water to the mill during the periods of time the pond volume in the TMF is not sufficient for reclaim (not realized in the PROJ-WQM). During closure, the WQM assumes the collection pond continues to collect seepage from the site but the water is directed to the open pit and not directly discharged from the mine site.

The PROJ-WQM predicts that all POIs will meet MDMER guidelines and acute water quality within the collection pond during operations, with the exception of the maximum predicted concentration exceeding short-term CWQG-FAL and MSOG-FAL ammonia guideline for the Upper Case scenario (modelled for contingency planning purposes). The predictions for the collection pond are shown in Table 4-7.

Table 4-5 Predicted Effluent Concentrations from the Collection Pond for all POIs that Exceed Guidelines for the Expected or Upper Case Scenarios

Parameter	Short-term CWQG-FAL (mg/L)	Short-term MSOG-FAL (mg/L)	MDMER Sched. 4 Limit (mg/L)[2]	Expected Case				Upper Case

Notes:
The proposed collection pond is planned to discharge to the receiving environment only during the Construction and Operations phases.
CWQG-FAL = Canadian Water Quality Guidelines - Freshwater Aquatic Life; MSOG-FAL = Manitoba Standards, Objectives, and Guidelines - Freshwater Aquatic Life; MDMER = Metal and Diamond Mining Effluent Regulations; (d) = dissolved
"Equation" = the guideline is dependent on hardness (except the MSOG-FAL ammonia guideline, which is dependent on pH). All hardness-depended guidelines were calculated on a month-by-month basis using predicted hardness in the collection pond (calculated from predicted Mg and Ca).
[1]Unionized ammonia (NH_3) was calculated from total ammonia (as N) using the CCME (2010) equation originally developed by Emerson et al (1975). Values for water temperature and pH were conservatively assigned 20 C and 8.5 for all calculations.
[2]Predictions were screened against the future MDMER Schedule 4 limits coming into force on June 1, 2021.
[3]The short-term MSOG-FAL for ammonia (as N) was calculated with a conservatively assumed pH of 8.5.

4.1.1.2 Open Pit Overflow

The predicted concentrations in the open pit increase throughout operations, as the pit expands, and additional mine rock is exposed. This water is directed to the collection pond. During closure the open pit collects contact water from the TMF, MRSA, and collection pond and a pit lake forms. Once the water level in the open pit reaches the overflow spillway, the surface water in the open pit will discharge to KEE3-B1 tributary (expected to occur between Year 34 and Year 36).

In the PROJ-WQM, the open pit is divided into shallow water (upper 15% of pit lake) and deeper water (lower 85% of pit lake) to simulate stratification. Initially, during closure, the predicted water quality in the open pit surfaces water is of significantly better water quality than bottom water. The reason for this is that the model assumes that all contact water is directed to the bottom of the open pit. The concentrations in the lower portion of the pit increases significantly at closure due to loads from the MRSA and TSF that are discharged to the pit at depth. During the initial years of post-closure, the predicted concentrations tend to increase as PAG rock at the site is assumed to load under locally acidic conditions; however, concentrations in the lower portion of the pit lake quickly reach steady state. Once the bottom water volume reaches 85% of the total pit capacity, the water at depth is assumed to mix with the surface water as there is no other outlet for this source.

Surface water in the open pit is initially of significantly better water quality than at depth (not shown); however, the surface water quality begins to deteriorate once the bottom of the pit begins to mix with the surface water. Overall, the predicted concentrations in the surface water are moderately lower than the concentrations at depth. The reason for this is that runoff from the area and precipitation on this pit only contributes to the surface water cell and provide a source of dilution. Further, some parameters undergo settling in the surface waters due to adsorption to organic matter/sediment and subsequent settling of this matter (arsenic, cadmium and copper). The predicted concentrations in the open pit surface water is presented in Table 4-8.

4.1.2 Receiving Environment Water Quality

The water quality predictions of the receiving environment are compared against long-term guidelines (CWQG-FAL and MSOG-FAL) at mixing cells (Appendix I). The POIs that are predicted to exceed long-term guidelines for the Expected Case are shown in Table 4-9.

Table 4-7 Parameters that Exceed Guidelines in the Receiving Environment from the Expected PROJ-WQM

Note: X indicates an exceedance of a water quality guidelines was identified

During operations, water from the mine site is discharged directly to the Keewatin River; however, during closure, the open pit discharges into a tributary of the Keewatin River, KEE3-B1. KEE3-B1 also received contact groundwater seepage from the MRSA and TMF as does the tributary north of the mine, KEE3-PAY1. Groundwater seepage is also predicted to discharge into Minton Lake, which is located outside of the Keewatin River catchment, in the Cockeram River catchment. To facilitate discussion of the predicted water quality in the receiving environment, the receiving environment is discussed in the following order:

- Tributaries to the Keewatin River
- Keewatin River
- Minton Lake and Cockeram River
- Cockeram Lake.

4.1.2.1 KEE3-B1 Tributary

The KEE3-B1 tributary is located downgradient from the mine. During operations, the overall area contributing to this catchment is reduced as the Project is located partially in this catchment and the tributary receives seepage from the MRSA and TSF (Upper Case only). During closure and post-closure, the tributary receives seepage from the MRSA and TSF (Expected and Upper Case) as well as overflow from the open pit. Particle tracking modelling (Stantec 2020b) shows that the majority of the bed seepage from the MRSA and TMF discharges immediately beneath the seepage collection ditch. In the winter (November to March) the PROJ-WQM assumes groundwater seepage that discharges to the tributary will freeze. However, the PROJ-WQM also assumes that in April, the seepage will thaw and contribute to loads in the tributary. This is considered a conservative assumption because in April runoff (source of dilution to the tributary) is minimal (i.e. snowmelt typically occurs in May and June). Therefore, while seepage is the dominate source of loadings to the stream, the model predicts that the highest concentrations occur in April. Once the open pit discharges into catchment, concentrations in the tributary throughout the year are predicted to increase; however, the maximum predicted concentrations during the winter tend to decrease.

The predictions for the KEE3-B1 node are considered conservative for several reasons, outlined below:

- The placement of ditches and water management activities can be optimized on the mine site to capture more bed seepage than was predicted by the groundwater model, as ditch location optimization was not conducted. During operations, it is likely a greater degree of seepage water will be captured in the ditches.
- The predictions assumed that groundwater flows prior to snowmelt (April). In reality, it is likely that the thawing of frozen water within the tributary will coincide with snowmelt.
- The PROJ-WQM assumes the open pit will discharge during the winter. However, this is unlike to occur due to ice formation in the open pit (not considered in the model). The most sensitive times correspond to predictions during the winter, when runoff is minimized. During the spring and summer, in the tributary, discharge from the open pit will be diluted with unimpacted catchment runoff.

- The model does not consider controlled pit lake semi-passive treatment strategies. Concentrations in the surface water of the open pit can be reduced by controlling stratification of the pit lake and amending the surface waters of the lake with fertilizer to promote biological activity. Trace metals will sorb to the organic matter in the lake which will settle out of the water column and accumulate in the sediment.
- The mean particle travel time from the TMF to KEE3-B1 indicates that the bulk of the seepage from the TMF is not expected to discharge into the tributary for 244 years. The travel time in the model was shortened to 80 years so that predictions could account for this source of water and predictions would remain conservative.

Phosphorus, fluoride, total aluminum, total arsenic, total cadmium, total copper, total manganese, and dissolved cadmium are predicted to exceed long-term guidelines in the Expected Case model run. Phosphorus and manganese are naturally elevated in the catchment. Fluoride, total cadmium, and total copper are largely the result of seepage that bypasses the collection ditch and can likely be managed by optimizing placement of the ditch and subsequently rerouting that seepage to the open pit. The PROJ-WQM predicts multiple exceedances of long-term guidelines for the Upper Case scenario, including fluoride, phosphorus, ammonia, nitrite, nitrate, cyanide, arsenic, aluminum, cadmium, copper, iron, nickel, selenium and zinc. As discussed in Section 4.1.1, the assumptions used to develop the predictions for the Upper Case scenario are highly conservative and are recommended to be used for contingency planning only. None the less, the large number of exceedances at this model node points to the potential need for additional waste management strategies to ensure that all seepage from the MRSA and TMF is collected during all phases of mine life.

4.1.2.2 KEE3-PAY1 Tributary

The KEE3-PAY1 tributary is located north of the mine and it discharges to the Keewatin upgradient of all point source discharges from the Project. The groundwater model predicts that baseflow in this tributary will increase; however, the actual seepage that enters the tributary from the mine site is predicted to be relatively low. As a result, the model predicts that water quality in the KEE3-PAY1 tributary will not change from baseline conditions for the Expected Case or Upper Case scenarios.

4.1.2.3 Keewatin River – QM03

The Keewatin River at model node QM03 receives discharge from the collection pond during operations. Correspondingly, during this time, concentrations in the river are predicted to increase. Predicted concentrations are not expected to exceed long term water quality guidelines in the river for the Expected Case. Total phosphorus, total iron and total cadmium and total zinc are predicted to exceed long term guidelines in the Upper Case scenario; however, total iron and total phosphorus naturally exceed in the baseline data and the elevated cadmium concentration results from source terms based on concentrations observed in one monitoring well (MW-11), which are above 10 x guidelines. It is possible that cadmium concentrations will be reduce through adsorption and settling in the collection pond as well as along the groundwater flow path.

4.1.2.4 Keewatin River – QM06

The model node QM06 in the Keewatin River receives discharge from the KEE-3B1 tributary during post closure as well as upstream loads from the QM03 model node during operations. Corresponding, concentrations increase during operations as a result of effluent from the collection pond (which discharges to QMO3). Concentrations tend to decrease during closure and post-closure until the open pit discharges to KEE3B1. This differs from water quality at KEE3-B1 in that the bed seepage from the MRSA and TMF had a measurable impact on discharge water quality predicted at KEE3-B1, as the seepage constituted a large component of the total flow in the tributary; however, the load from KEE3-B1 to the QMO6 model node is predicted to be relative small. Once the open pit overflows into the tributary, the load from the tributary to the Keewatin River increases.

Total aluminum is predicted to exceed long term guidelines in the Expected Case scenario at OQM06, and that is largely the result of elevated background concentrations. The Upper Case scenario predicts that fluoride, phosphorus, total cadmium, total copper, dissolved cadmium, dissolved nickel and dissolved zinc will exceed long term guidelines as result of the Project; however, Upper Case predictions are only recommended to be used for contingency waste management planning.

4.1.2.5 Keewatin River – QM05

The QMO5 model node receives loads from upstream in the Keewatin River as well as loads from Lynn River. As discussed as part of the validation process, this model node could not be validated and required further calibration; however, the model was validated against concentrations further downgradient in OQM08 (Cockeram River). Therefore, predicted concentrations are only compared to predicted baseline concentrations at this node. Overall, the predicted water quality for the Expected Case is not expected to exceed baseline concentrations by 20%.

4.1.2.6 Minton Lake

Minton Lake does not receive any point-discharge from the Project, but it does receive groundwater seepage from the MRSA and TMF. Water quality in Minton Lake naturally exceeds phosphorus and total aluminum guidelines. The catchment of Minton Lake is predicted to decrease but this only marginally impacts predicted concentrations during construction and operations for the Expected Case. Typically, the concentrations in the lake undergo two identifiable changes. The first change occurs when seepage from the MRSA discharges into the lake and the second change occurs when the TMF seepage discharges into the lake. For the Expected Case, seepage from the Project site does not result in POIs that exceed long term guidelines with the exception of total cadmium, which meets long term guidelines for the Expected Case. Cadmium is expected to be highly attenuated in the groundwater; however, a high degree of attenuation is not considered in the model. Furthermore, groundwater seepage from the MRSA is not expended to result in an exceedance of long term guidelines in the lake; however, the combined seepage from the TMF (which is predicted to take longer to discharge into the Lake) and the MRSA does result in the total cadmium exceedances. An assumption in the model is that seepage from the TMF discharges into the lake 80 years into closure. In fact, the groundwater model indicates that the mean travel time for this flow pathway is 847 years. Over this time frame, dispersion, attenuation and diffusion are likely to significantly decrease plume concentrations.

The Upper Case scenario concentrations predicted for Minton Lake exceed long term phosphorus (naturally elevated), fluoride, total arsenic (temporarily during operations), total aluminum (naturally elevated), total cadmium, total copper, and dissolved cadmium, dissolved nickel and dissolved zinc guidelines. It should be noted that nitrite is not predicted to exceed long term guidelines; however, it was identified as being underpredicted at the Minton Lake model node during model validation. Therefore, it is assumed for the purposes of these discussions, that it is also considered an exceedance as background nitrite concentrations in Minton Lake exceed long term guidelines.

The nitrite and arsenic exceedances are related to seepage from the MRSA reaching Minton Lake during operations. This is because the Upper Case seepage is predicted to reach the lake in 4 years (minimum observed particle tracking time). The mean particle travel time for this flow pathway is 77 years; and therefore, it is unlikely that the predicted upper-case concentrations will be observed in the Lake during operations. Although total aluminum is predicted to exceed guidelines, the predicted aluminum concentrations are within the observed variability at the site. Cadmium and copper, nickel and zinc are very likely to be attenuated along the groundwater flow path, especially considering the relative long travel time between the receptors.

4.1.2.7 Cockeram Lake

Cockeram Lake receives inflows from both the Keewatin River and Cockeram River (which receives loads from Minton Lake). For the Expected Case, total aluminum, total copper, total iron total nickel, dissolved copper, dissolved nickel and dissolved zinc, exceed long term water quality guidelines; however, the background concentrations also exceed guidelines at these locations. In all cases, the predicted concentrations are within the variability currently observed in the Lake and generally the result of loadings from the Lynn River. These same parameters are predicted to exceed guidelines for Upper Case scenario.

5.0 CONCLUSIONS

Stantec developed a comprehensive WBWQM to determine discharge rates and quality of effluent from the Project and predict impacts on the water quantity and water quality in the receiving environment. The WBWQM includes sub-models which simulate baseline conditions at each time step (BL-WBWQM). The impacts of the project were predicted using the PROJ-WBWQM and compared against the BL-WBWQM at each timestep in the model. The BL-WB was calibrated to observed flow data and the BL-WQM was validated against observed water quality data. Overall, the WBWQM is able to reasonably predict baseline flow rates and observed concentrations.

The significant findings for the WB regarding water quantity include the following:

- The flow is predicted to increase at QMO3 during operations due to discharge of effluent from the collection pond. The effluent discharge rate is predicted to range between 0 m3/s and 0.33 m3/s.

- The flow in QMO6 is predicted to increase during operations due to discharge from the collection pond. Flow at this node is also predicted to increase during post closure due to overflow from the open pit to the KEE3-B1 (QM04).
- The open pit is predicted to spill in Year 35 and the overflow rate is predicted to range between 0.01 m3/s and 1.19 m3/s.
- During operations and closure, the flow rate in the KEE3-B1 (QM04) tributary is predicted to decrease by 64% due to the decrease in catchment area.

The significant findings for the WQM regarding water quality include the following:

- The water quality of the collection pond effluent during operations is expected to meet MDMER and short-term guidelines for all POIs.
- The water quality of the open pit overflow during post-closure is expected to meet MDMER and short-term guidelines.
- The WQM predicts that total aluminum, total arsenic, total cadmium total copper, and dissolved cadmium may exceed long term water quality guidelines during post closure at KEE3-B1 as a result of the Project. The source of these POIs includes seepage from the MRSA (closure and post closure), discharge from the TMF (post-closure) and overflow from the open pit (post closure). It is likely the water quality in the KEE3-B1 catchment can be managed by capturing seepage beneath the MRSA and TMF facilities and redirecting this seepage to the open pit and by developing a pit lake fertilization program to promote the sorption of POIs to organic matter and subsequent settling of the organic matter and corresponding removal of the POIs from the pit lake surface water.
- The WQM predicts that total aluminum will exceed guidelines in the Keewatin River during post-closure at the outlet of KEE3-B1 (QM06); however, the variability in the background aluminum concentrations exceed the predicted aluminum concentrations at this location.
- The WQM predicts that total cadmium may exceed guidelines in Minton Lake during post-closure. However, this is predicated on the assumption that cadmium from the TMF will reach Minton Lake within 80 years. The mean travel time from the TMF to Minton Lake is 872 years. Over this time span, it is assumed that cadmium concentrations will be significantly reduced by dispersion, attenuation, and diffusion.

7.0 STANTEC QUALITY MANAGEMENT PROGRAM

This Technical Modelling Report entitled **Lynn Lake Gold Project Hydrology Water Balance and Water Quality Impact Assessment: MacLellan Site**, prepared for Alamos Gold Inc., dated April 30, 2020, was produced by Stantec Consulting Ltd.

This report was written by the following individual:

Katie Jones, P.Geo. (ON, BC), P.Chem. (BC)
Senior Geochemist

Signature

Nikolay Sidenko, Ph.D., P.Geo. (MB)
Senior Environmental Geochemist

Signature

This report was reviewed by the following individual:

David Luzi, Ph.D., P.Geo. (MB)
Senior Hydrologist

Signature

Approval to transmit to client:

Karen Mathers, M.Sc., P.Geo. FGC (MB), PMP
Senior Project Manager

Signature

This report was independently reviewed by Kara Hewgill, B.Sc., Principal

8.0 LIMITATIONS

This Technical Modelling Report entitled Lynn Lake Gold Project Hydrology Water Balance and Water Quality Impact Assessment: MacLellan Site was prepared by Stantec Consulting Ltd. ("Stantec") for the account of Alamos Gold Inc. (the "Client") to support the approvals and permitting process for the Lynn Lake Gold Project in Lynn Lake, Manitoba. In connection thereto, this document may be reviewed and used by the federal and provincial government agencies participating in the approvals and permitting process in the normal course of their duties; and stakeholders may provide comment as part of the regulatory approvals process. Except as set forth in the previous sentence, any reliance on this document by any third party for any other purpose is strictly prohibited. The material in it reflects Stantec's professional judgment in light of the scope, schedule and other limitations stated in the document and in the contract between Stantec and the Client. The opinions in contents of the document are based on conditions and information existing at the time the document was published and do not take into account any subsequent changes. In preparing the document, Stantec did not verify information supplied to it by others. Any unauthorized use that a third party makes of this document is the responsibility of such third party. Such third party agrees that Stantec shall not be responsible for costs or damages of any kind, if any, suffered by it or any other third party as a result of decisions made or actions taken based on unauthorized use of this document.

Predicted Lake Level for Cockeram Lake – 1:25 YR Wet Climate Scenario

Appendix E TABLES FOR WATER QUALITY MODEL INPUTS

Table E-1: Parameters selected for water quality model

Parameter name	Parameter Symbol	Name in model	Parameter group	Units	Guidelines/Limits		
					CWQG	MSOG	MDMER
pH	pH	pH	General chemistry	pH Unit	6.5-9.0	6.5-9.0	6.0-9.5
Proton	H+	Proton	General chemistry	mg/L	n/v	n/v	n/v
Acidity Total	Acid	Acidity_T	General chemistry	mg/L	n/v	n/v	n/v
Alkalinity Total	Alk	Alkalinity_T	General chemistry	mg/L	n/v	n/v	n/v
Bromide	Br	Bromide	General chemistry	mg/L	n/v	n/v	n/v
Chloride	Cl	Chloride	General chemistry	mg/L	120	n/v	n/v
Fluoride	F	Fluoride	General chemistry	mg/L	0.12	0.12	n/v
Sulfate	SO_4	Sulfate	General chemistry	mg/L	n/v	n/v	n/v
Phosphorus Total	P(T)	Phosphorus_T	Nutrients	mg/L	Narrative	0.025	n/v
Ammonia Nitrogen Total	$N\text{-}NH_3(T)$	N_Ammonia	Nutrients	N mg/L	Table 2	Equation*	n/v
Nitrite Nitrogen	$N\text{-}NO_2$	N_Nitrite	Nutrients	N mg/L	0.06	0.06	n/v
Nitrate and Nitrite Nitrogen	$N\ \text{-}NO_3\text{+}NO_2$	N_Nitrate_Nitrite	Nutrients	N mg/L	13	n/v	n/v
Cyanide Total	CN(T)	Cyanide_T	General chemistry	mg/L	n/v	n/v	0.5
Cyanide Free	CN(F)	Cyanide_F	General chemistry	mg/L	0.005	0.0052	n/v
WAD** Cyanide	CN(WAD)	Cyanide_WAD	General chemistry	mg/L	n/v	n/v	n/v
Hardness	Hard	Hardness	General chemistry	mg/L	n/v	n/v	n/v
Radium 226	Ra-226	Radium_226	Radioactivity	Bq/L	n/v	n/v	0.37
Total Suspended Solids	TSS	TSS	Supporting	mg/L	n/v	n/v	15
Aluminum Dissolved	Al(D)	Aluminum_D	Trace elements	mg/L	n/v	n/v	n/v
Aluminum Total	Al(T)	Aluminum_T	Trace elements	mg/L	0.005/0.1	0.005/0.1	n/v
Antimony Dissolved	Sb(D)	Antimony_D	Trace elements	mg/L	n/v	n/v	n/v
Antimony Total	Sb(T)	Antimony_T	Trace elements	mg/L	n/v	n/v	n/v
Arsenic Dissolved	As(D)	Arsenic_D	Trace elements	mg/L	n/v	0.15	0.3
Arsenic Total	As(T)	Arsenic_T	Trace elements	mg/L	0.005	n/v	0.3
Barium Dissolved	Ba(D)	Barium_D	Trace elements	mg/L	n/v	n/v	n/v
Barium Total	Ba(T)	Barium_T	Trace elements	mg/L	n/v	n/v	n/v
Beryllium Total	Be(T)	Beryllium_T	Trace elements	mg/L	n/v	n/v	n/v
Boron Dissolved	Be(D)	Boron_D	Trace elements	mg/L	n/v	n/v	n/v
Boron Total	B(T)	Boron_T	Trace elements	mg/L	1.5	1.5	n/v
Cadmium Dissolved	Cd(D)	Cadmium_D	Trace elements	mg/L	n/v	Equation*	n/v
Cadmium Total	Cd(T)	Cadmium_T	Trace elements	mg/L	Equation**	n/v	n/v
Calcium Dissolved	Cd(D)	Calcium_D	General chemistry	mg/L	n/v	n/v	n/v
Chromium Dissolved	Cr(D)	Chromium_D	Trace elements	mg/L	n/v	Equation*	n/v
Chromium Hexavalent Dissolved	Cr(VI)	Chromium_D_Hex	Trace elements	mg/L	0.001	0.001	n/v
Chromium Total	Cr(T)	Chromium_T	Trace elements	mg/L	0.0089	n/v	n/v

See Notes on next page

Parameter name	Parameter Symbol	Name in model	Parameter group	Units	Guidelines/Limits		
					CWQG	MSOG	MMER
Cobalt Dissolved	Co(D)	Cobalt_D	Trace elements	mg/L	n/v	n/v	n/v
Cobalt Total	Co(T)	Cobalt_T	Trace elements	mg/L	n/v	n/v	n/v
Copper Dissolved	Cu(D)	Copper_D	Trace elements	mg/L	n/v	Equation*	0.3
Copper Total	Cu(T)	Copper_T	Trace elements	mg/L	Equation**	n/v	0.3
Iron Dissolved	Fe(D)	Iron_D	Trace elements	mg/L	n/v	n/v	n/v
Iron Total	Fe(T)	Iron_T	Trace elements	mg/L	0.3	0.3	n/v
Lead Dissolved	Pb(D)	Lead_D	Trace elements	mg/L	n/v	Equation*	0.1
Lead Total	Pb(T)	Lead_T	Trace elements	mg/L	Equation**	n/v	0.1
Magnesium Dissolved	Mg(D)	Magnesium_D	General chemistry	mg/L	n/v	n/v	n/v
Manganese Dissolved	Mn(D)	Manganese_D	General chemistry	mg/L	Table 5	n/v	n/v
Manganese Total	Mn(T)	Manganese_T	General chemistry	mg/L	Table 5	n/v	n/v
Mercury Dissolved	Hg(D)	Mercury_D	Trace elements	mg/L	n/v	n/v	n/v
Mercury Total	Hg(T)	Mercury_T	Trace elements	mg/L	0.000026	0.000026	n/v
Molybdenum Dissolved	Mo(D)	Molybdenum_D	Trace elements	mg/L	n/v	n/v	n/v
Molybdenum Total	Mo(T)	Molybdenum_T	Trace elements	mg/L	0.073	0.073	n/v
Nickel Dissolved	Ni(D)	Nickel_D	Trace elements	mg/L	n/v	Equation*	0.5
Nickel Total	Ni(T)	Nickel_T	Trace elements	mg/L	Equation**	n/v	0.5
Potassium Dissolved	K(D)	Potassium_D	General chemistry	mg/L	n/v	n/v	n/v
Selenium Dissolved	Se(D)	Selenium_D	Trace elements	mg/L	n/v	n/v	n/v
Selenium Total	Se(T)	Selenium_T	Trace elements	mg/L	0.001	0.001	n/v
Silicon Dissolved	Si(D)	Silicon_D	General chemistry	mg/L	n/v	n/v	n/v
Silicon Total	Si(T)	Silicon_T	Trace elements	mg/L	n/v	n/v	n/v
Silver Dissolved	Ag(D)	Silver_D	Trace elements	mg/L	n/v	n/v	n/v
Silver Total	Ag(T)	Silver_T	Trace elements	mg/L	0.00025	0.0001	n/v
Sodium Dissolved	Na(D)	Sodium_D	General chemistry	mg/L	n/v	n/v	n/v
Sodium Total	Na(T)	Sodium_T	General chemistry	mg/L	n/v	n/v	n/v
Strontium Dissolved	Sr(D)	Strontium_D	Trace elements	mg/L	n/v	n/v	n/v
Strontium Total	Sr(T)	Strontium_T	Trace elements	mg/L	n/v	n/v	n/v
Thallium Dissolved	Tl(D)	Thallium_D	Trace elements	mg/L	n/v	n/v	n/v
Thallium Total	Tl(T)	Thallium_T	Trace elements	mg/L	0.0008	0.0008	n/v
Uranium Dissolved	U(D)	Uranium_D	Trace elements	mg/L	n/v	n/v	n/v
Uranium Total	U(T)	Uranium_T	Trace elements	mg/L	0.015	0.015	n/v
Vanadium Total	V(T)	Vanadium_T	Trace elements	mg/L	n/v	n/v	n/v
Zinc Dissolved	Zn(D)	Zinc_D	Trace elements	mg/L	Equation**	Equation*	0.5
Zinc Total	Zn(T)	Zinc_T	Trace elements	mg/L	n/v	n/v	0.5

Table E-1: Parameters selected for water quality model

Notes:

The most stringent guideline was selected when two or more guidelines are established for the same parameter under the same jurisdiction (CCME, MWS, or Government of Canada).

CWQG - Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life (CWQG-FAL referred to as CWQG) by Canadian Council of Ministers of the Environment (CCME 2020).

MSOG - Manitoba Water Quality Standards Objectives and Guidelines for Freshwater Aquatic Life - Manitoba (MWS 2011).

MDMER - Metal and Diamond Mining Effluent Regulations (Canada), Schedule 4 - Authorized Limits of Deleterious Substances, Maximum Authorized Monthly Mean Concentrations (SOR/2002-222 2020).

ᵞ Guidelines are for pH; pH = - Lg[H^+] where [H^+] is a molar concentration of protons.

Equations were used to calculate hardness, pH, temperature, and DOC-dependent guidelines for these parameters as per MWS (Equation*) and CCME (Equation**):

- Total cadmium CWQG-FAL: at hardness > 280 mg/L the guideline is 0.00037 mg/L, at hardness between 17 and 280 mg/L the guideline (in mg/L) is 0.001*[10^(1.016*(log10(Hardness))-1.71)], at hardness < 17 mg/L the guideline is 0.00011 mg/L.
- Total copper CWQG: When the water hardness is 0 to < 82 mg/L the CWQG is 0.002 mg/L, at hardness ≥82 to ≤180 mg/L the CWQG is calculated as CWQG (µg/L) = 0.2 * $e^{\{0.8545[\ln(hardness)]-1.465\},\ a}$t hardness >180 mg/L the CWQG is 0.004 mg/L, if the hardness was unknown the CWQG was 0.002 mg/L.
- Total lead CWQG: When the hardness is 0 to ≤ 60 mg/L the CWQG is 0.001 mg/L, at hardness >60 to ≤ 180 mg/L the CWQG is calculated as CWQG (µg/L)= $e^{\{1.273[\ln(hardness)]-4.705\},}$ at hardness >180 mg/L the CWQG is 0.007 mg/L, if the hardness was unknown the CWQG was 0.001 mg/L.
- Dissolved manganese CWQG-FAL (mg/L): pH and hardness-dependent guideline calculated based on the CWQG and benchmark calculator in Appendix B or Table 5 of the Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life: Manganese (Dissolved) 2019 (CCME 2019).
- Total nickel CWQG: When the water hardness is 0 to ≤ 60 mg/L the CWQG is 0.025 mg/L, at hardness > 60 to ≤ 180 mg/L the CWQG is calculated as CWQG (µg/L) = $e^{\{0.76[\ln(hardness)]+1.06\}}$.
- Dissolved zinc CWQG-FAL: exp(0.947[ln(Hardness)] - 0.815[pH] + 0.398[ln(DOC)] + 4.625). The value for DOC was set at 0.3 mg/L (i.e., the lowest and most conservative value to calculate the guideline).
- Ammonia MSOG: [(0.0577/1+$10^{7.688-pH}$)+(2.487/1+$10^{pH-7.688}$)]*a, where a=2.85 or a=1.45*$10^{0.028*(25-Temperature)}$, whichever is less and pH ≥6.5 and ≤9.0.
- Dissolved cadmium MSOG (µg/L): [$e^{\{0.7409[\ln(Hardness)-4.719\}}$]*[1.101672-{ln(Hardness)(0.041838}].
- Dissolved chromium MSOG (µg/L): [($e^{(0.819*(\ln(Hardness)) + 0.6848)}$)]*[0.86]
- Dissolved copper MSOG (µg/L): [$e^{\{0.8545[\ln(Hardness)]-1.702\}}$]*[0.960].
- Dissolved lead MSOG (µg/L): [$e^{\{1.273[\ln(Harness)-4.705\}}$]*[1.46203-{ln(Hardness)(0.145712)}].
- Dissolved nickel MSOG (µg/L): [$e^{\{0.8460[\ln(Hardness)]+0.0584\}}$]*[0.997].
- Dissolved zinc MSOG (µg/L): [$e^{\{0.8473\{\ln(Hardness)]+0.884\}}$]*[0.986].

Manitoba Tier II guidelines for dissolved metals are based on exceedance once in three years, but not more frequent, being acceptable during periods of infrequent and extreme low stream flows.

- CWQG for total phosphorus: Canadian Guidance Frameworks is used for total phosphorus (CCME 2014): ultra-oligotrophic <4 µg/L, oligotrophic 4-10 µg/L, mesotrophic 10-20 µg/L, meso-eutrophic 20-35 µg/L, eutrophic 35-100 µg/L, hyper-eutrophic >100 µg/L.
- Ammonia CWQG: pH and temperature-dependent guideline for total ammonia as N presented in Table 2 of the CWQG guidelines for the protection of aquatic life: Ammonia (CCME 2010). The values from Table 2 are multiplied by 0.8224 to convert them into total ammonia (as N).
- Ammonia MSOG-FAL: pH and temperature-dependent guideline, see Equation 1 values from Table 1 in MWS (2011).
- Nitrate and Nitrite Nitrogen: CWQG for nitrate is applied.
- Aluminum CWQG: 0.1 mg/L if pH>6.5, otherwise 0.005 mg/L.

Table E-2: Chemistry inputs to model cells

Source/Mixing cell (Station ID used for initial cell concentration*)	Description of local Subcatchment/Source Cell with Constant Concentration	Subcatchment/Cell ID in the water quality model	Water Quality Station ID Used for Source Cell Input
Keewatin River Upstream of Mine Discharge/QM02_CT (AQM4)	Burge Lake Outflow	QM01_CT	AQM4
	Keewatin watershed between Burge and Dot lakes	WS_QM2_CT	AQM4
	Payne Lake tributary	Kee3_Pay1_CT	AQM31
	Keewatin watershed south of Payne Lake tributary	Kee3_4_CT	AQM4
	Tributary West of waste rock pile	Kee3_C1_CT	AQM4
Keewatin River at Collection Pond and Open Pit Discharge/QM03_CT (AQM7)	Dot Lake Outflow	QM09_CT	AQM5
	Keewatin watershed south of Dot lake	WS_QM3_CT	AQM7
	Watershed on eastern bank of Keewatin downstream of the bridge	Kee3_1_3	AQM7
Keewatin River Upstream of the Confluence with Lynn River/QM06_CT (AQM8)	East Pond tributary	Kee3_B1_CT	AQM18
	Watershed on western bank of Keewatin upstream of PHWY391	WS_QM06_CT	AQM8
	Watershed between Keewatin and Minton lake	Kee3_A1_CT	AQM8
Keewatin River at Confluence with Lynn River/QM05_CT (AQM29)	Lynn River Inflow to Keewatin	WS_QM05_CT	AQM28
Minton Lake/Minton_Lake_CT (AQM16)	Tributary draining watershed North of Minton Lake	MIN5_CT	AQM16
	Minton Lake Watershed	MIN4_CT	AQM16
Cockeram River/QM10_CT (AQM10)	Combined Lobster and Huet Lake Watersheds	WS_QM10_CT	AQM10
Cockeram Lake/Cockeram_Lake_CT (AQM11)	Cockeram Lake Watershed minus QM10 watershed	WS_QM08_CT	AQM11
NA	Site runoff to the TMF	Overland_Runoff_TMF_CT	
NA	Site runoff to the collection pond	Overland_Runoff_CP_CT	AQM18
NA	Site runoff to the Open Pit	Overland_Runoff_OP_CT	
NA	Overburden Aquifer Inflow to the Open Pit	OP_Bedrock_Inflow_CT	Overburden
NA	Bedrock Aquifer Inflow to the Open Pit	OP_Overburden_Inflow_CT	Bedrock
NA	Overburden Aquifer Inflow to Minton Lake	Groundwater_CT	Overburden
NA	Bedrock Aquifer Inflow to Minton Lake	Groundwater_CT	Bedrock

Table E-3-1: Observed water quality - mean

Note:

- Yellow indicates that the values were manipulated according to the following prescriptions:
  - If dissolved fraction > total, then dissolved fraction = total fraction;
  - If dissolved Cr VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved Cr;
  - If free cyanide > WAD cyanide, then free cyanide = WAD cyanide;
  - If WAD cyanide > total cyanide, then WAD cyanide = total cyanide;
  - If nitrite (as N) > nitrate + nitrite (as N), then nitrite (as N) = nitrate + nitrite (as N).

Note:

- Yellow indicates that the values were manipulated according to the following prescriptions:
  - If dissolved fraction > total, then dissolved fraction = total fraction;
  - If dissolved Cr VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved Cr;
  - If free cyanide > WAD cyanide, then free cyanide = WAD cyanide;
  - If WAD cyanide > total cyanide, then WAD cyanide = total cyanide;
  - If nitrite (as N) > nitrate + nitrite (as N), then nitrite (as N) = nitrate + nitrite (as N).

Table E-3-1: Observed water quality - mean

Note:

- Yellow indicates that the values were manipulated according to the following prescriptions:
  - If dissolved fraction > total, then dissolved fraction = total fraction;
  - If dissolved Cr VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved Cr;
  - If free cyanide > WAD cyanide, then free cyanide = WAD cyanide;
  - If WAD cyanide > total cyanide, then WAD cyanide = total cyanide;
  - If nitrite (as N) > nitrate + nitrite (as N), then nitrite (as N) = nitrate + nitrite (as N).

Note:

- Yellow indicates that the values were manipulated according to the following prescriptions:
  - If dissolved fraction > total, then dissolved fraction = total fraction;
  - If dissolved Cr VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved Cr;
  - If free cyanide > WAD cyanide, then free cyanide = WAD cyanide;
  - If WAD cyanide > total cyanide, then WAD cyanide = total cyanide;
  - If nitrite (as N) > nitrate + nitrite (as N), then nitrite (as N) = nitrate + nitrite (as N).

Note:

- Yellow indicates that the values were manipulated according to the following prescriptions:
  - If dissolved fraction > total, then dissolved fraction = total fraction;
  - If dissolved Cr VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved C
  - If free cyanide > WAD cyanide, then free cyanide = WAD cyanide;
  - If WAD cyanide > total cyanide, then WAD cyanide = total cyanide;
  - If nitrite (as N) > nitrate + nitrite (as N), then nitrite (as N) = nitrate + nitrite (as N).

Note:

- Yellow indicates that the values were manipulated according to the following prescriptions:
  - If dissolved fraction > total, then dissolved fraction = total fraction;
  - If dissolved Cr VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved Cr;
  - If free cyanide > WAD cyanide, then free cyanide = WAD cyanide;
  - If WAD cyanide > total cyanide, then WAD cyanide = total cyanide;
  - If nitrite (as N) > nitrate + nitrite (as N), then nitrite (as N) = nitrate + nitrite (as N).

Note:

- Yellow indicates that the values were manipulated according to the following prescriptions:
  - If dissolved fraction > total, then dissolved fraction = total fraction;
  - If dissolved Cr VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved Cr;
  - If free cyanide > WAD cyanide, then free cyanide = WAD cyanide;
  - If WAD cyanide > total cyanide, then WAD cyanide = total cyanide;
  - If nitrite (as N) > nitrate + nitrite (as N), then nitrite (as N) = nitrate + nitrite (as N).

Note:

- Yellow indicates that the values were manipulated according to the following prescriptions:
  - If dissolved fraction > total, then dissolved fraction = total fraction;
  - If dissolved Cr VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved Cr;
  - If free cyanide > WAD cyanide, then free cyanide = WAD cyanide;
  - If WAD cyanide > total cyanide, then WAD cyanide = total cyanide;
  - If nitrite (as N) > nitrate + nitrite (as N), then nitrite (as N) = nitrate + nitrite (as N).

Note:

- Yellow indicates that the values were manipulated according to the following prescriptions:
  - If dissolved fraction > total, then dissolved fraction = total fraction;
  - If dissolved Cr VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved Cr;
  - If free cyanide > WAD cyanide, then free cyanide = WAD cyanide;
  - If WAD cyanide > total cyanide, then WAD cyanide = total cyanide;
  - If nitrite (as N) > nitrate + nitrite (as N), then nitrite (as N) = nitrate + nitrite (as N).

Note:

- Yellow indicates that the values were manipulated according to the following prescriptions:
  - If dissolved fraction > total, then dissolved fraction = total fraction;
  - If dissolved Cr VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved Cr;
  - If free cyanide > WAD cyanide, then free cyanide = WAD cyanide;
  - If WAD cyanide > total cyanide, then WAD cyanide = total cyanide;
  - If nitrite (as N) > nitrate + nitrite (as N), then nitrite (as N) = nitrate + nitrite (as N).

Appendix F OXYGEN DIFFUSION MODEL IN TMF

Memo

To:	LLGP Project Team	From:	Mark Steinepreis Waterloo, Ontario
File:	By email	Date:	September 12, 2017

Reference: Infiltration of precipitation and oxygen gas through the proposed MacLellan TMF

Unsaturated seepage analyses have been carried out to determine the relative infiltration of precipitative water and oxygen gas that could be expected through the crest of the MacLellan TMF before and after a soil cover is placed. The software SEEP/W from the Geo-studio suite of software has been used for this task.

It is notable that the majority of the material available on site is till, but contains little clay. The overburden material seems to be particularly sandy within the footprint of the pit, the stockpile of which will be the source for cover material. Little resistance to infiltration would be through the coarser cover material, and therefore percolation through the underlying tailings would be unchanged or potentially even increase. A possible explanation for the latter is if precipitation on exposed fine tailings runs off instantaneously during the event, but the tailings receives a steady supply of infiltration after the placement of the cover and has a greater ability to accept it.

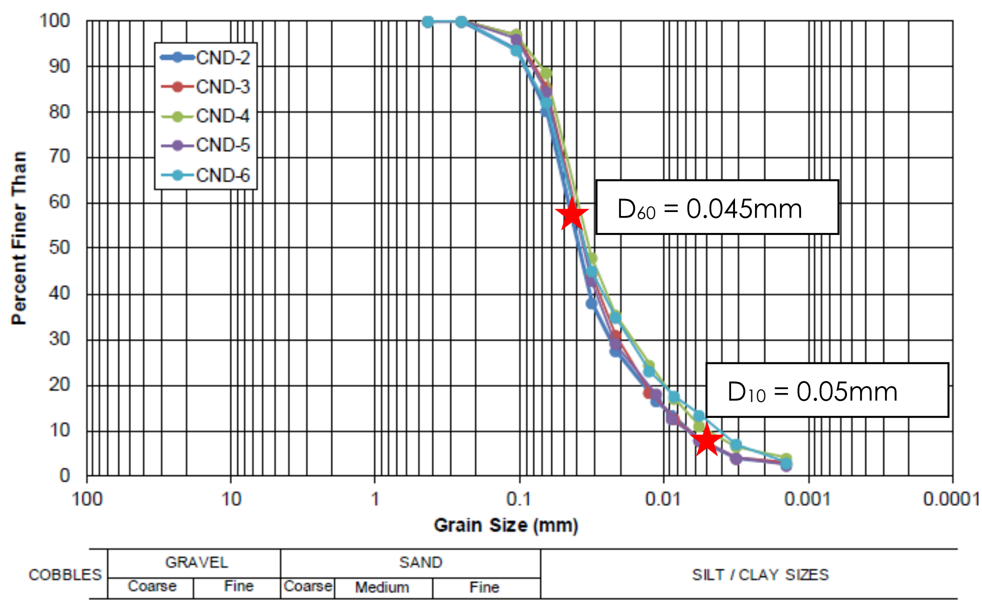
MATERIAL PARAMETERS

Volumetric water content (VMC) and unsaturated hydraulic conductivity functions are required for all materials for the unsaturated flow analysis. The software has internal capability to estimate the VMC function based on data from particle size distribution (PSD) tests, and uses a Van Genuchten fit for the unsaturated-k function.

WATER FLOW PROPERTIES - TAILINGS

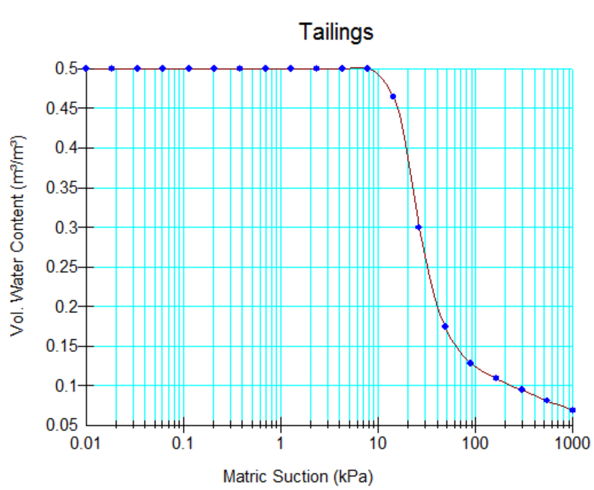
Golder (2016) was used to obtain PSD inputs for function estimations. The D_{60} and D_{10} are required, and the approximate values for the tailings are shown in the Figure below:

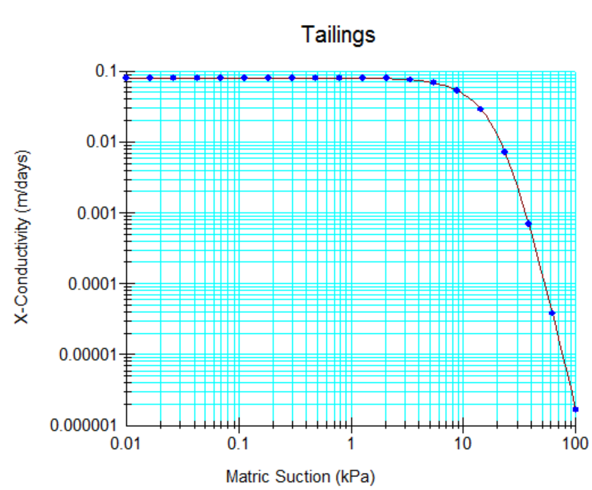
Reference: Infiltration of precipitation and oxygen gas through the proposed MacLellan TMF



The hydraulic conductivity of the tailings material was estimated from the Rowe Cell data. The noted value for hydraulic conductivity at a confining pressure of 10kPa represents the figure for half (0.5) metres below the surface, which is a reasonable value to apply to the tailings material in the model. The sample was tested at 85% saturation, so the saturated hydraulic conductivity was input such that the value at 85% saturation matched the value from the Rowe cell data. The saturated MC of the material is approximately 0.5, again from the Rowe Cell data, which is a typical value for tailings. Analysis was considered with a variable hydraulic conductivity with depth, however numerical issues with the oxygen gas modelling were observed.

The resulting VMC and hydraulic-k functions that were formulated by the software are shown below:



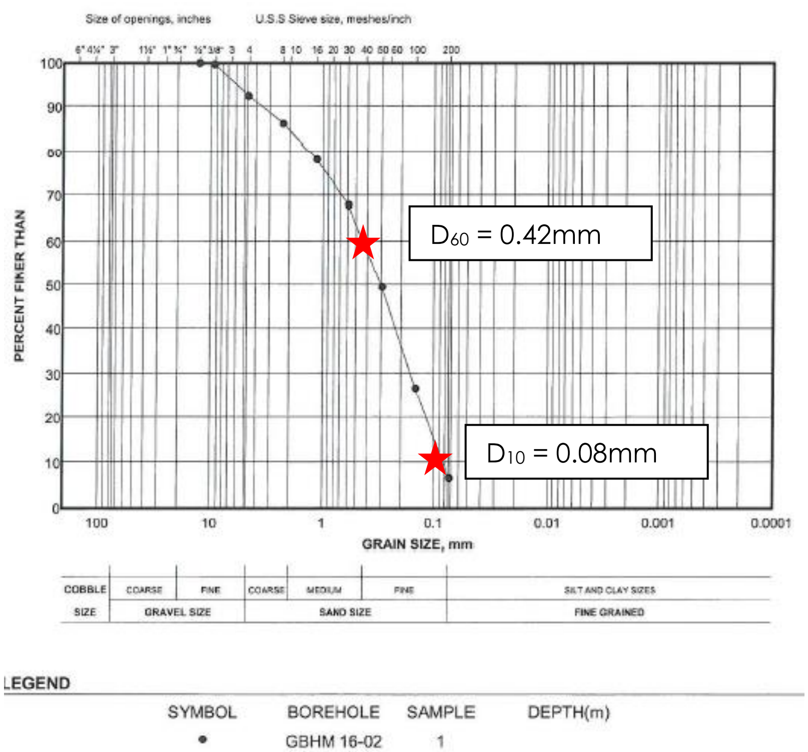


Reference: Infiltration of precipitation and oxygen gas through the proposed MacLellan TMF

WATER FLOW PROPERTIES - COVER MATERIAL

The cover material will come from the overburden stockpile, which contains the excavated surficial material from within the pit footprint. Boreholes from with the pit indicate that the material is sandy and has a very small fines content, potentially less than 10%. This is not ideal for a cover, however the material should at least provide some means for revegetation.

The PSD of the overburden at borehole GBHM 16-02 is shown below, along with the D_{60} and D_{10} that were used as model inputs. This borehole is within the footprint of the pit.

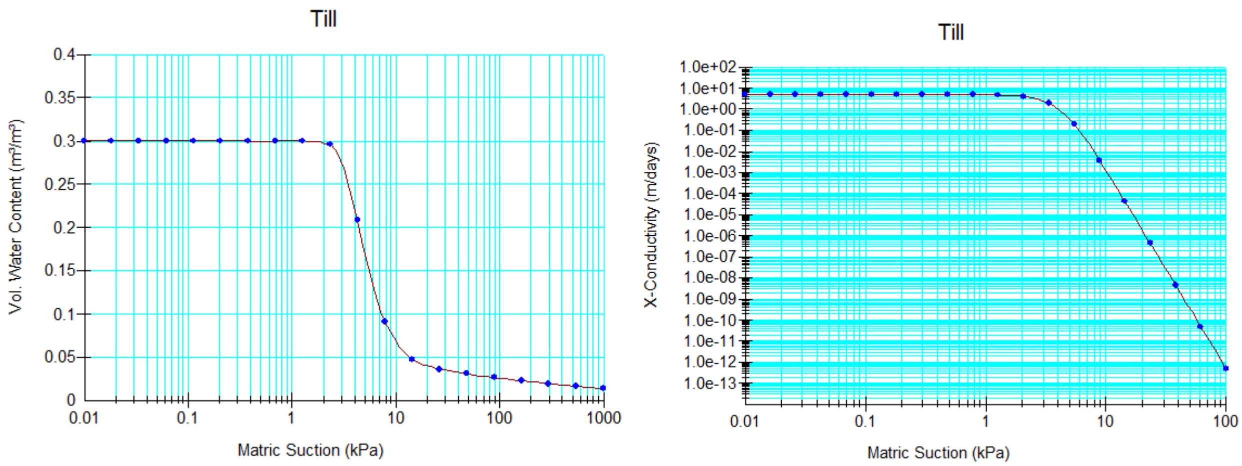


Falling and rising head permeability tests were carried out within this strata in GBHM16-01 and 02. An average result of 6×10^{-6} m/s (0.5 m/day) is indicated in the Golder report. Moisture content results of samples from those holes indicate the material was at approximately 15% (Geotech water content, i.e. M_w/M_s, which is approximately equal to M_w/M_t). Assuming a reasonable value of n = 0.3 for most soils, the material was at 50% saturation.

Similar to the tailings, the saturated hydraulic conductivity was varied until the value at 50% saturation was 0.5 m/day.

The VMC function and hydraulic-k function that were prepared by the software are shown below:

Reference: Infiltration of precipitation and oxygen gas through the proposed MacLellan TMF



OXYGEN CONSUMPTION / DIFFUSION PROPERTIES - TAILINGS

The assumption in the software is that the supply of oxygen in tailings is diffusion dominated. This is reasonable in this situation due to the fine nature of the material.

The bulk diffusion coefficient of oxygen was estimated according to Aachib et al., (2004):

$$D^{*}\theta_a = \frac{1}{n^2}(D_a^0 \theta_a^x)$$

Where:

D^* = bulk diffusion coefficient (m^2/s)

θ_a = air content (m^3/m^3)

n = porosity

x = $1.201\theta_a^3 - 1.515\theta_a^2 + 0.987\theta_a + 3.119$

D_a^0 = $1.8x10^{-5}$ (m^2/s)

An expression for K_r is shown in Mbonimpa (2003):

$$Kr = K' \frac{6}{D_H}(1-n)C_P$$

$$D_H = [1 + 1.17 log(Cu)]D_{10}$$

where:

K' = the reactivity of pyrite with oxygen (15.8×10^{-3} m^3 O_2 m^{-2} pyrite.$year^{-1}$)

C_p = Pyrite content of dry tailings (kg/kg)

Reference: Infiltration of precipitation and oxygen gas through the proposed MacLellan TMF

C_U = Coefficient of conformity (D_{60}/D_{10})

D_{10} – diameters corresponding to 10% passing on the cumulative grain-size distribution curve.

It is notable that the expression assumes that the sulfide mineral is pyrite. It is not known how the presence of other sulfides might affect the results. A review of the geochemistry results for the ore and synthetic tailings indicates that a sulfide content for the tailings of 3% is a reasonable assumption. The other parameters are available, and the input Kr value for the tailings was 0.44 days^{-1} .

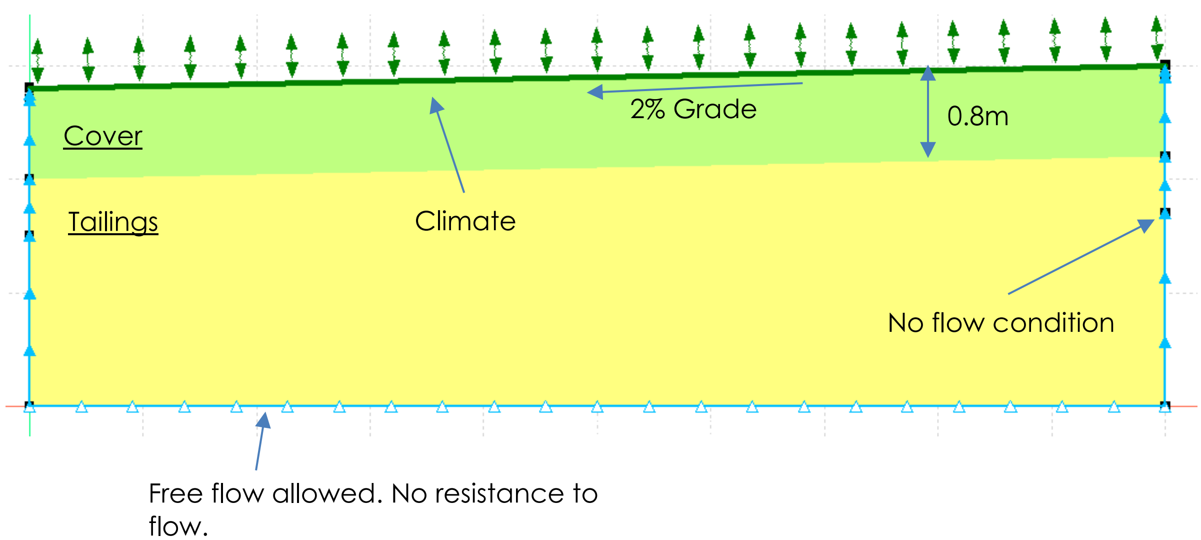
GEOMETRY AND BOUNDARY CONDITIONS

The purpose of the analysis was to answer the question 'how much does infiltration decrease through the tailings when a cover is placed on top…?'. To answer this, it is not necessary to do an analysis for freeze/thaw conditions because those types of conditions can be taken care of separately within the water balance.

A simplified climate was considered as a boundary condition applied at the crest of the tailings/cover, with alternating days of average precipitation and no precipitation (to allow evaporation to occur). Evaporation was considered by the software using average summertime temperature and relative humidity as inputs.

Model geometry was for a 0.8m thick layer of cover material over tailings. A grade of 2% was applied to the crest to make allowance for some runoff. The model geometry and boundary conditions are shown below.

The model geometry and boundary conditions are shown on the Figure below. The model was run with the bare tailings, and then with the cover placed above.



Reference: Infiltration of precipitation and oxygen gas through the proposed MacLellan TMF

INITIAL CONDITIONS

The water table was assumed to be initially at 0.5m below the surface of the tailings. The cover is assumed to be placed instantaneously at approximately w=15% by weight, approximately equal to the measured w at the time of the fieldwork. The latter is applied as a pressure head, i.e. the suction that corresponds with the proposed w is obtained from the VMC and applied as an initial condition in the software.

RESULTS – INFILTRATION

The high permeability / low precipitation nature of this scenario results in little difference in infiltration into the tailings before and after the cover is placed (Figure 1 and Figure 2; the output flux is for a 10m wide simulated tailings model and is provided for comparative purposes only). A point of 2.0m below the crest of the tailings has been selected as the comparison point, as the results at the crest of the tailings are complicated by evaporative and precipitative effects.

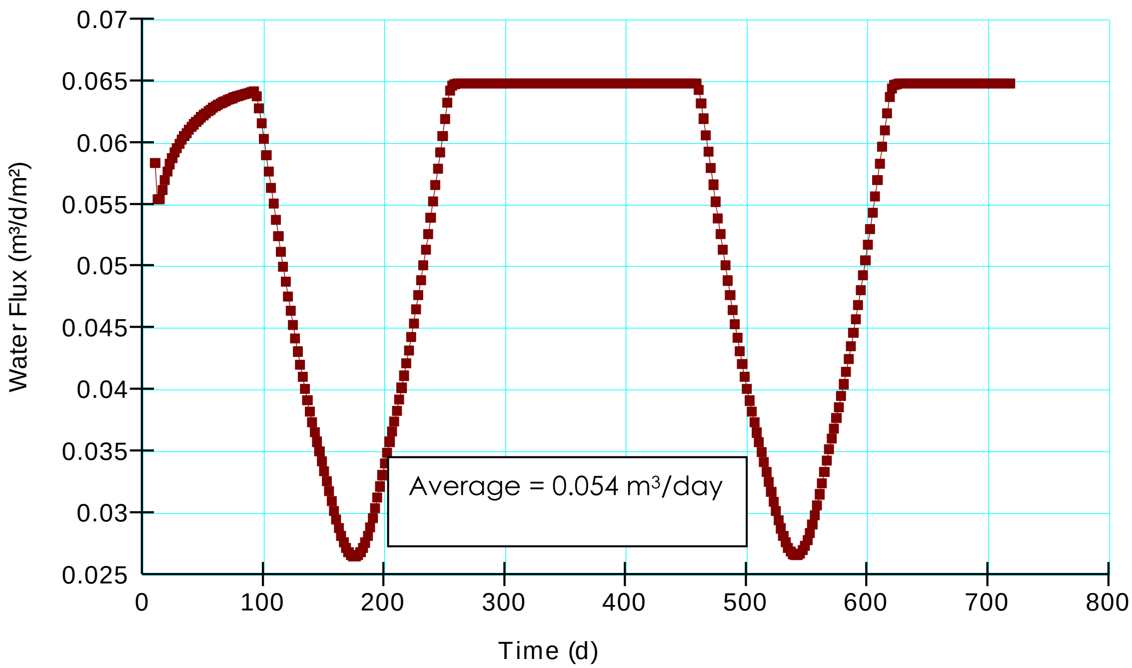


Figure 1 – Water flux at 2m below the tailings, before placement of cover

Reference: Infiltration of precipitation and oxygen gas through the proposed MacLellan TMF

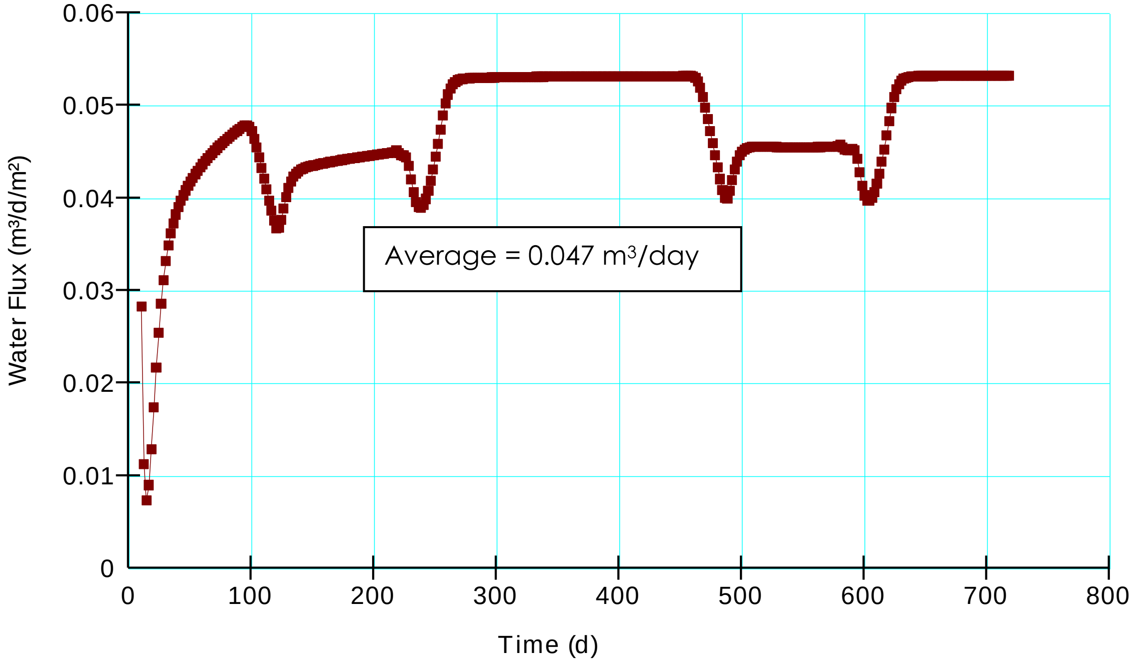

Figure 2 – Water flux at 2m below the tailings, after placement of cover

RESULTS – O_2 DIFFUSION

A steady state between the consumption of O_2 and the diffusion coefficient of the materials is reached quickly. The high sulfide content will remove the oxygen out of the system and the tailings are likely to be poorly oxygenated within 1.0m of the crest of the tailings whether or not the cover is in place. Figure 3 presents a typical oxygen profile with depth before and after the cover is placed.

Reference: Infiltration of precipitation and oxygen gas through the proposed MacLellan TMF

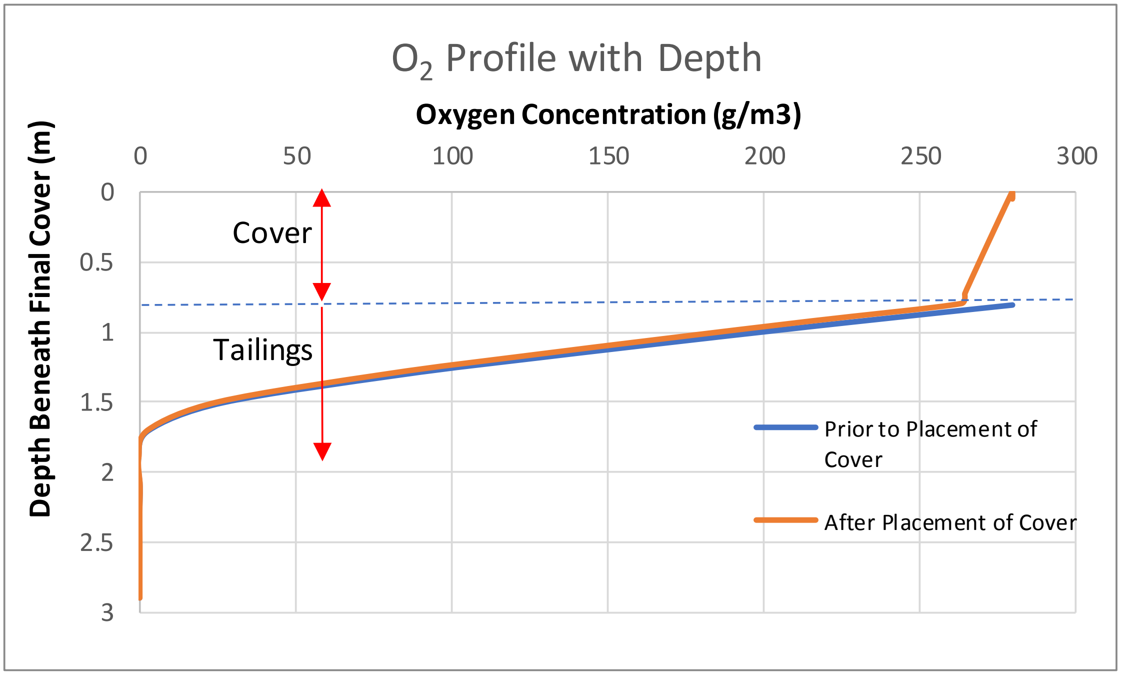

Figure 3 – Oxygen profile with depth before and after a cover is placed

Appendix G SUMMARY OF WATER QUALITY MODEL PREDICTIONS

Summary Table

Appendix Title and Model Scenario	Notes	Nodes Included
MacLellan Site Receiving Environment Predicted Water Quality for the Expected Case	Monthly mean, median and maximums for each project phase; percent increase from baseline; Indicate parameters that exceed water quality guidelines CCME short: **Bold** CCME long: *Italic* MWQG short: Single Underline	QM02_CT, QM03_CT, QM06_CT, QM05_CT, Kee3_Pay1_CT, Kee3_B1_CT, Minton_Lake_CT, QM10_CT, QM08_CT
MacLellan Site Receiving Environment Predicted Water Quality for the Upper Case		QM02_CT, QM03_CT, QM06_CT, QM05_CT, Kee3_Pay1_CT, Kee3_B1_CT, Minton_Lake_CT, QM10_CT, QM08_CT
MacLellan Site Contact Water Quality for the Expected Case	Monthly mean, median and maximums for each project phase; Indicate parameters that exceed water quality guidelines CCME short: Bold MWQG short: Italic MDMER: Single Underline	Collection_Pond, OP_CT, TMF_cell_CT
MacLellan Site Contact Water Quality for the Upper Case		Collection_Pond, OP_CT, TMF_cell_CT

Notes for contact water discharges:

Dashed lines represent "not applicable".
Bold font indicates the monthly average concentration exceeds the short-term CWQG.
Italic font indicates the monthly average concentration exceeds the short-term MSOG.
Underline indicates monthly average concentration exceeds the metal and diamond mine effluent regulations.
CWQG-FAL = Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life by Canadian Council of Ministers of the Environment (CCME 2017).
MSOG-FAL = Manitoba Water Quality Standards Objectives and Guidelines for Freshwater Aquatic Life - Manitoba (MWS 2011).
[a] Manitoba Tier II guidelines for dissolved metals are based on exceedance once in three years, but not more frequent, being acceptable during periods of infrequent and extreme low stream flows.
* Equations were used to calculate hardness (as CaCO3), pH, DOC, and temperature-dependent guidelines for these parameters as per MWS (2011) and CCME (2017).
- Ammonia MSOG-FAL: pH and temperature-dependent guideline. Values used for screening are based on Equation 1 values from Table 1 in MWS (2011)
- Ammonia CWQG-FAL: pH and temperature-dependent guideline. Values used for screening are based on Table 1 in CCME (2010) and converted to ammonia (as N) by multiplying the unionized ammonia (NH_3) guidelines by 0.8224.
- Dissolved cadmium MSOG-FAL (mg/L): 0.001*[(exp(0.7409*(ln(Hardness))-4.719))*(1.101672-(ln(Hardness)*0.041838))]
- Dissolved chromium MSOG-FAL (mg/L): 0.001*[(exp(0.819*(ln(Hardness)) + 0.6848))*(0.86)]
- Dissolved copper MSOG-FAL (mg/L): 0.001*[exp(0.8545[ln(Hardness)]-1.702]*[0.960]
- Dissolved lead MSOG-FAL (mg/L): 0.001*[(exp(1.273*(ln(Hardness)) - 4.705))*((1.46203-(ln(Hardness))*0.145712))]
- Dissolved nickel MSOG-FAL (mg/L): 0.001*[(exp(0.846*(ln(Hardness))+0.0584))*(0.997)]
- Dissolved manganese CWQG-FAL (mg/L): pH and hardness-dependent guideline. Values used for screening are based on Table 5 in CCME (2019).
- Dissolved zinc MSOG-FAL (mg/L): 0.001*[(exp(0.8473*(ln(Hardness))+0.884))*(0.986)]
- Dissolved zinc CWQG-FAL: exp(0.947[ln(Hardness)] - 0.815[pH] + 0.398[ln(DOC)] + 4.625). The value for DOC was set at 0.3 mg/L (i.e., the lowest and most conservative value to calculate the guideline)
- Total cadmium CWQG-FAL: at hardness > 280 mg/L the guideline is 0.00037 mg/L; at hardness between 17 and 280 mg/L the guideline (in mg/L) is 0.001*[10^(1.016*(log10(Hardness))-1.71)]; at hardness < 17 mg/L the guideline is 0.00011 mg/L.
- Total copper CWQG-FAL: at hardness > 180 mg/L the guideline is 0.004 mg/L; at hardness between 82 and 180 mg/L the guideline (in mg/L) is 0.001*0.2*[exp(0.8545*(ln(Hardness]))-1.465)]; at hardness < 82 mg/L the guideline is 0.002 mg/L.
- Total lead CWQG-FAL: at hardness > 180 mg/L the guideline is 0.007 mg/L; at hardness between 60 and 180 mg/L the guideline (in mg/L) is 0.001*[exp(1.273*(ln(Hardness]))-4.705)]; at hardness < 60 mg/L the guideline is 0.001 mg/L.
- Total nickel CWQG-FAL: at hardness > 180 mg/L the guideline is 0.15 mg/L; at hardness between 60 and 180 mg/L the guideline (in mg/L) is 0.001*[exp(0.76*(ln(Hardness]))+1.06))]; at hardness < 60 mg/L the guideline is 0.025 mg/L.

Notes for receiving environment:

Dashed lines represent "not applicable".
Bold font indicates the monthly average concentration exceeds the short-term CWQG.
Italic font indicates the monthly average concentration exceeds the long-term CWQG.
Underline indicates monthly average concentration exceeds the short-term MSOG.
Shaded background indicates the monthly average concentration exceeds the long-term MSOG.
