1.0 INTRODUCTION

The Lynn Lake Gold Project (LLGP; or "the Project") consists of two primary deposit sites, which are both located near Lynn Lake, Manitoba: the 'Gordon' site and the 'MacLellan' site. Alamos Gold Inc. (Alamos) intends to construct (redevelop), operate and close/reclaim open pit gold mines at both these historical mine sites. The Gordon site is located approximately 55 kilometres (km) east of Lynn Lake, Manitoba (by vehicle), and the MacLellan site is located approximately 8 km northeast of Lynn Lake (by vehicle). The distance between the Gordon and MacLellan sites is approximately 57 km (by vehicle). Lynn Lake is located approximately 820 km northwest of Winnipeg.

This Air Quality Assessment has been completed to determine potential residual and cumulative changes to ambient air quality as a result of the Project (Maps 1 and 2, Appendix A). The Final EIS Guidelines for the Lynn Lake Gold Project (CEAA 2017) identify the Project components and residual effects to be included in the air quality assessment.

The air quality assessment estimates air emissions from the planned Project activities and uses an atmospheric dispersion model to predict the potential changes in ambient air quality associated with Project emissions. The GHGs assessment considers emissions of greenhouse gases (GHGs) expressed in the form of tonnes of carbon dioxide equivalent (CO_{2e}) and compares them to provincial and national emission totals.

The air quality assessment considers substances for which there are applicable ambient air quality criteria (AAQC) and standards adopted by the Manitoba Sustainable Development (MSD, now Manitoba Conservation and Climate [MCC]), the Ontario Ministry of the Environment and Climate Change (MOECC) and Environment and Climate Change Canada (ECCC). The predicted air quality changes are assessed relative to these criteria, presented in Section 2.1.

The primary pathway for the air contaminants to reach human and ecological receptors is via airborne dispersion and deposition during Project activities. As a result, the key objective of the air quality assessment is to provide predicted ambient concentrations and depositions due to Project emissions for the following Valued Components (VC) of the EIS:

- Surface Water – Project emissions and the deposition of these emissions may affect water quality of surrounding lakes and streams.
- Fish and Fish Habitat - Project emissions and the deposition of these emissions may affect water quality of surrounding lakes and streams and changes in water quality may affect the availability and suitability of fish habitat and affect the growth, survival, and health of fish.
- Vegetation and Wetlands - Project fugitive dust emissions and the deposition of these emissions on surrounding native plant communities may affect plant species diversity, community diversity and wetland functions.

- Wildlife and Wildlife Habitat – Project emissions and the associated ambient concentrations and deposition may increase the exposure of wildlife to air contaminants and affect wildlife health.

- Human Health - Project emissions and the associated ambient concentrations may increase the exposure of humans to air contaminants that may affect human health. The deposition of Project emissions to soil may affect soil quality which may, in turn, alter soil-related exposures for human receptors.

This report is presented in 13 sections. The purpose of the air quality assessment is provided in Section 1, along with a description of the substances of interest and assessment boundaries. The regulatory criteria used in the assessment is discussed in Section 2 and an overview of the regional setting is provided in Section 3. Project air emissions and Project GHG emissions are discussed in Sections 4 and 5, respectively. Section 6 contains environmental control and management procedures. Sections 7 and 8 present the assessment approach and dispersion modelling results, respectively. Model prediction uncertainty is discussed in Section 9 and concluding remarks are provided in Section 10. Lastly, references cited are listed in Section 11, following by Stantec's Quality Management section and the report limitations as Sections 12 and 13, respectively.

1.1 SUBSTANCES OF INTEREST

1.1.1 Substances of Interest for the Air Quality Assessment

The air quality assessment considers substances for which there are applicable AAQC and standards adopted by either provincial (Manitoba) or federal regulatory agencies. The air quality assessment includes the following substances:

- Nitrogen dioxide (NO_2).

- Carbon monoxide (CO).

- Sulphur dioxide (SO_2).

- Hydrogen Cyanide (HCN).

- Total suspended particulate matter (TSP) with an aerodynamic diameter less than 30 µm.

- Respirable particulate matter (PM_{10}) with an aerodynamic diameter less than 10 µm.

- Fine particulate matter ($PM_{2.5}$) with an aerodynamic diameter less than 2.5 µm.

- Total particulate deposition (dustfall).

- Metals (arsenic, cadmium, copper, lead, nickel, zinc).

The primary substances considered in the air quality assessment (NO_2, CO, SO_2, TSP, PM_{10}, $PM_{2.5}$ and lead) are defined by the United States Environmental Protection Agency (US EPA) as criteria air contaminants (CACs) because there are objectives, standards, or criteria governing their concentration in ambient air. Henceforth, these are collectively referred to as the applicable ambient air quality criteria (AAQC) or criteria.

1.1.2 Substances of Interest for the Human Health Assessment

Also considered in the air quality assessment are diesel particulate matter (DPM), individual volatile organic compounds (VOCs), polycyclic aromatic hydrocarbons (PAHs) and broader spectrum of metal species (seven metal species associated with diesel exhaust and 18 metal species contained in ore, mine rock, overburden and tailings). VOCs and PAHs emissions from the Project are associated entirely with diesel exhaust. Predicted ambient concentrations of these substances due to the Project are provided for the human health assessment .

1.1.3 Greenhouse Gases

The GHG assessment considers the following substances:

- Carbon dioxide (CO_2)
- Methane (CH_4)
- Nitrous oxide (N_2O)

The GHG assessment considers the GHG substances that are known to be emitted by the Project. It is recognized that GHGs also include perfluorocarbons (PFC), hydrofluorocarbons (HFC), and sulfur hexafluoride (SF_6). These gases are expected to be released in insubstantial amounts or not at all, and therefore are not included in the GHG assessment.

1.2 ASSESSMENT BOUNDARIES

1.2.1 Spatial Boundaries

1.2.1.1 PDA

The proposed Project Development Area (PDA) encompasses the immediate area in which Project activities and components may occur plus a 30 m buffer and is the anticipated area of direct physical disturbance associated with construction and operation of the Project (i.e., the Project footprint). The PDA includes the access roads, the open pits, mine rock storage areas, overburden stockpiles, and ore stockpiles at the Gordon and MacLellan sites; and the TMF and ore milling and processing plant at the MacLellan site. The PDA does not include Provincial Road 391 (PR 391) that connects the Gordon and MacLellan sites because PR 391 is an existing public road that is not part of the Project footprint; however, PR 391 is included in the LAA/RAA described below. Truck traffic associated with ore haulage from the

Gordon site to the ore milling and processing plant at the MacLellan site will generate emissions. The extent of the PDA at the Gordon and MacLellan sites are shown on Map 3 in Appendix A.

1.2.1.2 LAA and RAA

The Local Assessment Area (LAA) and Regional Assessment Area (RAA) for air quality were established to comply with provincial regulatory requirements and to capture air quality effects of the specific components being assessed. The LAA is the maximum area where Project-specific environmental effects on air quality can be predicted or measured with a reasonable degree of accuracy and confidence. The LAA includes the PDA. The RAA represents the area within which cumulative effects on air quality are likely to occur, depending on the location of other past, present, or reasonably foreseeable future projects or activities.

Both the LAA and RAA are defined as a 50 km by 28 km area centered on the Project and include both the Gordon and MacLellan sites. This area of the modelling domain is large enough to predict ground-level concentrations for comparison with the relevant AAQC. The LAA and RAA are consistent with regulatory recommendations in the draft Guidelines for Air Dispersion Modelling in Manitoba (Manitoba Conservation 2006). This modelling domain is used for both the LAA and RAA and is the area over which dispersion modelling was completed and the area over which graphical results of the air quality modelling are presented. Map 3 in Appendix A shows the LAA/RAA for air quality.

1.2.1.3 Project Boundary

The air quality assessment focuses on areas that are located outside industrial facility boundaries. A facility boundary is a fence line that indicates the region where public access is restricted. AAQC are only applied to areas where there is public access (i.e., on and beyond the facility boundary). Setting the facility boundary for a mine is less straightforward than for a fenced facility such as a pulp mill. In the instance of a fenced mill, the facility's physical fence line defines where public access is restricted. Mines are not generally fenced; however, public access is often discouraged or prohibited due to safety concerns.

For the air quality assessment, a "Project Boundary" was used to better represent the potential for public exposure and compliance with AAQC. The Project Boundary is defined as an outline around the PDA at the Gordon and MacLellan sites with a buffer of 300 m. The Project Boundary also includes PR 391 with a 300 m buffer on each side of the road. The selected Project Boundary agrees with the Manitoba Hunting Guide (MSD 2019a) which prohibits hunting within 300 m of any quarry or mineral mine. Local populations have been notified of the prohibited zone, therefore instances of members of the public being located within the hunting prohibited zone are expected to be infrequent and brief. The extent of the Project Boundary used in the air quality assessment is shown on Map 3 in Appendix A.

1.2.2 Temporal Boundaries

1.2.2.1 Project Phases

The temporal boundaries for the Project consist of the following phases:

- Construction – two years (Year -2, Year -1; scheduled to be carried out concurrently at both sites).
- Operation – 13 years (scheduled to be carried out from Year 1 through Year 6 at the Gordon site and from Year 1 through Year 13 at the MacLellan site).
- Decommissioning/closure – 5-6 years of active closure at each site followed by approximately 10 years of post-closure monitoring and approximately 50+ years of pit flooding at each site.

1.2.2.2 Selected Worst-Case Years for Project Construction and Operation

The worst-case years for Project construction and operation were assessed for air quality with the understanding that the other years will have a lower level of potential residual effects on air quality. The worst-case years of construction and operation coincide with the peak construction and production rate, respectively, that will result in the highest emissions of air contaminants. The worst-case year of construction was selected based on the most overlapping (e.g., coincidental) construction activities, the largest number of construction equipment units and the highest construction material movement. The worst-case year for operation was selected based on the highest production rate, largest number of mining equipment units and highest movement of overburden, mine rock and ore (measured in tonnes). The 12-month period from Q2 Year -2 to Q1 Year -1 was determined as the worst-case year of construction for both the Gordon and MacLellan sites. Year 2 was determined to be the worst-case year of operation for the Gordon site and Year 7 the worst-case year of operation for the MacLellan site.

2.0 REGULATORY CRITERIA

2.1 AMBIENT AIR QUALITY CRITERIA

The applicable regulatory criteria for this assessment include the Manitoba AAQC (MSD 2005), Ontario's AAQC (MOECC 2012), and the Canadian Ambient Air Quality Standards (CAAQS; CCME 2017). These are provided in Table 2-1. The Manitoba ambient air quality criteria include two concentration levels: Maximum Acceptable Level Concentrations and Maximum Desirable Level Concentrations; the most stringent Maximum Desirable Levels are used in the air quality assessment. There are no Manitoba AAQC for VOCs, PAHs and metals other than the six metal species included in the air quality assessment. Therefore, the model predicted ambient concentrations of VOCs, PAHs and metals due to the Project are provided for the human health assessment.

The CAAQS were developed as part of the Air Quality Management System (AQMS; CCME 2012a) with the objective of driving continuous improvement of air quality in Canada. The Canadian Council of Ministers of the Environment (CCME) describes the process for selecting monitoring stations, measuring pollutant concentrations and determining achievement of the CAAQS (CCME 2019; CCME 2012b). Determining achievement of the CAAQS is based upon the measured air quality concentrations at community monitoring stations with comparison to the CAAQS and assigning air quality status to one of four management levels (CCME 2019; CCME 2012b). The four air quality management levels require progressively more rigorous actions by jurisdictions as air quality approaches or exceeds the CAAQS, thereby allowing proactive management actions to be undertaken to reduce emissions and avoid exceedances of the CAAQS (CCME 2019).

The CCME guidance on determining achievement of the CAAQS (CCME 2019) states that: "*CAAQS were not developed as facility level regulatory standards. Rather, they are used by provinces and territories to guide air zone management actions intended to reduce ambient concentrations below the CAAQS and prevent CAAQS exceedances*". In this context, predicted ambient concentrations due to the Project are compared to the CAAQS for information purposes and do not imply compliance with the AAQC at the Project Boundary.

Table 2-1 Applicable Regulatory Criteria

Substance	Averaging Period	Manitoba Ambient Air Quality Criteria [a] (µg/m³)		Ontario Ambient Air Quality Criteria [b] (µg/m³)	Canadian Ambient Air Quality Standards [c] (µg/m³)

NOTES:

[a] Manitoba Ambient Air Quality Criteria (MSD 2005)

[b] Ontario Ambient Air Quality Criteria (MOECC 2012)

[c] Canadian Ambient Air Quality Standards (CCME 2017)

[d] The 1-hour CAAQS for NO_2 is referenced to the three-year average of the annual 98th percentile of the NO_2 daily maximum 1-hour average concentrations (effective 2025) (CCME 2017).

[e] The annual CAAQS for NO_2 is referenced to the arithmetic average over a single calendar year of all 1-hour average NO_2 concentrations (effective 2025) (CCME 2017).

[f] The 1-hour CAAQS for SO_2 is referenced to the three-year average of the annual 99th percentile of the SO_2 daily maximum 1-hour average concentrations (effective 2025) (CCME 2017).

[g] The annual CAAQS for SO_2 is referenced to the arithmetic average over a single calendar year of all 1-hour average SO_2 concentrations (effective 2025) (CCME 2017).

[h] Annual geometric mean

[i] The CAAQS for 24-hour $PM_{2.5}$ is referenced to the annual 98th percentile of daily 24-hour average concentrations, averaged over three years (effective 2020) (CCME 2017).

[j] The CAAQS for annual $PM_{2.5}$ is referenced to the three-year mean of annual average concentrations (effective 2020) (CCME 2017).

"—" not available

Values in **BOLD** text represent the ambient air quality criteria that are used for the environmental assessment

2.2 INTERPRETATION OF PREDICTED CONCENTRATIONS AND DEPOSITIONS

The AAQC are developed for a time-averaging period (e.g., 1-hour, 24-hour) and have a specific statistical form referred to as a "metric" (e.g., 98th percentile, 99.9th percentile).

Based on the ADMG Ontario (MOECC 2016), certain extreme, rare, and transient meteorological conditions may be present in the data sets and may be considered as outliers that can be eliminated from the model results. When assessing model predicted 1-hour average concentrations, the eight highest meteorological hours in each modelled year are considered meteorological anomalies and the ninth highest value was used for comparison with the 1-hour AAQC. Similarly, when assessing predicted 24-hour average concentrations, the highest meteorological day in each modelled year is considered a meteorological anomaly and the second highest value is used for comparison with the 24-hour average AAQC.

The model predicted dustfall from the Project is compared to the Ontario AAQCs. The 30-day dustfall is expressed as an accumulated deposition over one month (mg/dm^2/30-day). Therefore, the 30-day dustfall AAQC is interpreted as a limit on the monthly average deposition for the worst month of the year. The annual dustfall is expressed as a geometric mean of the monthly accumulated depositions (mg/dm^2/30-day). Therefore, the annual dustfall AAQC is interpreted as a limit on the average monthly deposition for the year.

Compliance with the 24-hour CAAQS for $PM_{2.5}$ is based on the three-year average of the 98^{th} percentile annual value, which allows the highest seven predicted 24-hour average $PM_{2.5}$ concentrations in a year to be disregarded. For this assessment, the 8^{th} highest 24-hour average $PM_{2.5}$ concentration (equal to the 98^{th} percentile) for each year at a given location are used to determine compliance with the 24-hour CAAQS. The 8^{th} highest predicted 24-hour average $PM_{2.5}$ concentrations for each year are averaged over three years and the maximum of the three-year averages is compared to the 24-hour CAAQS.

Similarly, the 1-hour CAAQS for NO_2 and SO_2 are based on the three-year average of the 98^{th} percentile and 99^{th} percentile, respectively, of the daily maximum 1-hour concentration, which allows the highest seven and three predicted daily maximum 1-hour average concentrations in a year, respectively, to be disregarded. For this assessment, the 8^{th} highest daily 1-hour average NO_2 concentrations (equal to the 98^{th} percentile) for each year at a given location are used to determine compliance with the 1-hour NO_2 CAAQS. The 4^{th} highest daily 1-hour average SO_2 concentrations (equal to the 99^{th} percentile) for each year at a given location are used to determine compliance with the 1-hour SO_2 CAAQS.

The air quality assessment focuses on areas that are located outside industrial facility boundaries. A facility boundary is a fence line that indicates the region where public access is restricted. AAQC are only applied to areas where there is public access (i.e., on and beyond the facility boundary). For this assessment, a "Project Boundary" was used to better represent the potential for public exposure and compliance with AAQC. The Project Boundary for the air quality assessment is defined as an outline around the PDA at Gordon and MacLellan sites and PR 391 with a buffer of 300 m.

3.0 REGIONAL SETTING

3.1 GEOGRAPHICAL SETTING

The Project is in North Central Manitoba, approximately 322 km northwest of Thompson, 1,085 km northwest of Winnipeg (by vehicle), and 100 km east of Kinoosao, Saskatchewan (by vehicle). The Project is in a remote, sparsely populated and rugged region of the Churchill River Upland Ecoregion of the Boreal Shield Ecozone (Smith et al. 1998).

The surface topography in the ecoregion is partly related to the underlying bedrock structure and partly related to the glacial and postglacial history. The terrain consists of mostly hilly, till veneered bedrock, with intervening low areas of organic terrain. Topography slopes from a high of 450 m above mean sea level (amsl) in the west and northwest to a low of 260 m amsl in the southeast. Surface topography surrounding the Project is flat to gently undulating, with local relief generally averaging 10 to 25 m. Elevation ranges from 312 masl to 351 masl at the Gordon Site, and 323 masl to 379 masl at the MacLellan Site.

Numerous wetlands, lakes, rivers, and streams are found throughout the area due to impermeable bedrock and poorly drained soils. These waterbodies are a part of the Churchill River Watershed that drains into the Hudson Bay to the east.

Forestry and mining activities are primary resource uses occurring in northern Manitoba. Hunting, trapping, water-oriented recreation, including sport fishing, and tourism are important activities. There are two communities near the Project: Town of Lynn Lake and Black Sturgeon Reserve. These communities are connected by PR 391, which runs southeast from Lynn Lake to the Town of Leaf Rapids and the City of Thompson.

3.2 CLIMATE AND METEOROLOGY

Climate is defined as the weather conditions prevailing in an area in general or over a long time period and is described in terms of average and extreme weather conditions that occur over a 30-year period. These statistical summaries are referred to as Climate Normals. Climate Normals were obtained for the most recent 30-year period 1981 to 2010 from the Lynn Lake Airport climate station (ECCC 2019a) located approximately 7 km southwest of the Project. The climate data collected and analyzed at this station includes ambient air temperature and precipitation. Additional hourly wind data was obtained for 2015 to 2018 to provide a more refined understanding of local winds. Given the proximity of Lynn Lake Airport to the Project and the relatively uniform topographical and ground cover conditions, the meteorological conditions at the Lynn Lake Airport are expected to be representative of the LAA. The full assessment of climate and meteorology baseline conditions is presented in the Climate and Meteorology Baseline Technical Data Report (TDR; Stantec 2017a) and associated Validation TDR (Stantec 2020a).

The Project lies in the Reindeer Lake Ecodistrict of the Boreal Shield Ecozone. The Boreal Shield Ecozone occupies central Manitoba north and east of Lake Winnipeg, and south of the Taiga Shield Ecozone. The Boreal Shield Ecozone is extensively forested while the Taiga Shield Ecozone forms the transition from the Boreal Shield Ecozone to the south to the treeless Southern Arctic Ecozone to the north (Smith et al. 1998).

The Reindeer Lake Ecodistrict lies within a warmer, more humid subdivision of the Boreal Shield Ecozone. It has a strong continental climate which is characterized by long, cold winters and short, cool summers. In the Reindeer Lake Ecodistrict summers are cool and short on average, however warm days are quite common. Winters are long and cold. The mean annual temperature is about -3.1°C, average growing season is 136 days, and the number of growing degree-days is around 970 (Smith et al. 1998).

Mean annual precipitation in the Reindeer Lake Ecodistrict is about 480 mm, of which more than one-third falls as snow. Precipitation varies greatly from year to year and is highest during late spring through early summer. The average yearly moisture deficit (i.e., the difference between evaporation and precipitation) is nearly 60 mm (Smith et al., 1998).

The climate baseline assessment for the LAA is based on the 30-year Climate Normals data (1981 to 2010) from the Lynn Lake Airport climate station. The average and extreme monthly summaries of ambient temperature and precipitation are presented in Table 3-1.

The mean annual temperature for the 30-year interval is -3.2°C. The coldest monthly average temperature is -24°C (January) and the highest monthly average temperature is 16°C (July). The total annual precipitation is 478 mm, with 318 mm falling as rain, and the remainder as snow. July is the wettest month (85 mm, all as rain), while February is the driest month (16 mm, nearly all as snow). The total average snowfall is 208 cm, with the highest snowfall occurring in November (36 cm).

The hourly wind speed and direction data from Lynn Lake airport for 2015 to 2018 were analyzed. These data are summarized in Table 3-2 and Figure 3-1. Table 3-2 shows that the annual average wind speed is 3.7 m/s (13 kph) with little variation in monthly average winds over the year. The maximum hourly wind speed (13.9 m/s or 50 kph) was observed in June. Monthly average wind speeds are lowest in December and hourly maximum wind speeds are lowest in August. Winds are generally from the northwest in colder months, and easterly in the warmer months.

Figure 3-1 illustrates the annual wind speed and wind direction statistics for Lynn Lake Airport (2015-2018) in the form of a wind rose and a wind frequency distribution diagram. The wind rose illustrates that winds generally prevail from the northwest quadrant with the most frequent and strongest winds (> 6 m/s or 22 kph) originating from that direction. Easterly and southerly winds are also predominant. Southwesterly and northeasterly winds are less predominant and generally less frequently strong. Winds are between 2 m/s and 4 m/s (7 kph and 14 kph) occur 41% of the time. Calm winds (< 1 m/s or 3.6 kph) are not recorded at Lynn Lake Airport climate station.

3.3 BASELINE AMBIENT AIR QUALITY

The baseline ambient air quality was determined based on analysis of ambient air quality monitoring data from local monitoring of $PM_{2.5}$, PM_{10} and dustfall conducted during the air quality baseline field programs in 2015 and 2016 and from other more distant monitoring stations in Manitoba and the Northwest Territories for NO_2, SO_2 and CO, which were not measured during the field programs. The baseline ambient air quality concentrations used in other approved projects in Manitoba were also reviewed.

More detailed information about the local baseline ambient air quality monitoring programs is presented in the Air Quality Baseline TDR (Stantec 2017b) and associated Validation TDR (Stantec 2020b).

3.3.1 Local Baseline Monitoring Program

A local baseline ambient air quality monitoring program in 2015 and 2016 included data collection from two $PM_{2.5}$ and PM_{10} continuous monitoring stations and seven passive dustfall monitoring stations in the LAA. The monitoring program was conducted during summer months to coincide with snow-free conditions when exposed surfaces will generate the highest concentrations of ambient particulate matter (PM). During the first months of the monitoring program in 2015 (late June and early July), air emissions

Table 3-1 Baseline Climate Data Summary based on Lynn Lake Airport Climate Normals (1981-2010)

from forest fires in northern Saskatchewan and Manitoba influenced the PM readings and the measurements of dustfall. Therefore, baseline levels for PM and dustfall were derived based only on the 2016 measurements.

Ambient concentrations of $PM_{2.5}$ and PM_{10} were measured at the MacLellan site during summer 2015 and 2016, and at Black Sturgeon Reserve during fall 2015. The monitoring location at the MacLellan site was selected due to its proximity to the community of Lynn Lake. The $PM_{2.5}$ and PM_{10} measurements at the MacLellan site were affected by forest fires in northern Manitoba and Saskatchewan in late June and early July 2015. The Black Sturgeon Reserve was added to the monitoring program to provide baseline data for that community, which is closer to the Gordon site. Monitoring of $PM_{2.5}$ and PM_{10} at Black Sturgeon Reserve occurred in late September and early October 2015 and therefore, the measurements were not biased by the forest fires in summer. The monitoring at Black Sturgeon Reserve was not continued in 2016 as the data collected during 2015 was considered sufficient to establish a baseline.

Monthly dustfall amounts in milligrams per square decimeter per day ($mg/dm^2/day$) were measured at four sites in summer 2015 (the MacLellan site, Burge Lake, Lynn Lake and Farley Lake). To gain additional understanding of baseline conditions along PR 391, three dustfall monitoring stations were added in summer 2016 to the existing four: Cockeram Lake, Westdal Lake and Black Sturgeon Reserve Road. Map 4 in Appendix A shows the locations of the baseline ambient air quality monitoring stations.

During one sampling period in summer 2015 and one sampling period in summer 2016, dustfall samples were analyzed for metals (33 metal species) to determine baseline metal deposition values that were used in the human health assessment.

In March 2016, three bulk snow samples were collected from the Gordon site and three bulk snow samples were collected from the MacLellan site. The locations of the snow collection sites are shown in Map 4 in Appendix A. The snow samples were analyzed to determine baseline snow surface loading rates for total metals deposition.

3.3.1.1 $PM_{2.5}$ Concentrations

The 24-hour $PM_{2.5}$ measurements at the MacLellan site and Black Sturgeon Reserve are summarized in Table 6-7. There were 67 complete days of $PM_{2.5}$ measurements (i.e., more than 18 hours in each 24-hour period) at the MacLellan site out of 113 total monitoring days in 2015, and 105 complete days out of 114 total monitoring days in 2016. The average and maximum $PM_{2.5}$ concentrations for the 67 complete days in 2015 are 11.4 and 99.4 $\mu g/m^3$, respectively. The average and maximum $PM_{2.5}$ concentrations for the 105 complete days in 2016 are 2.9 and 10.5 $\mu g/m^3$, respectively. There are 17 complete days of $PM_{2.5}$ measurements at Black Sturgeon Reserve out of 19 total monitoring days in 2015; the average and maximum $PM_{2.5}$ concentrations for these 17 days are 0.5 and 2.3 $\mu g/m^3$, respectively.

The results indicate that the maximum measured $PM_{2.5}$ concentrations at the MacLellan site during 2015 are greater than the CAAQS (27 $\mu g/m^3$). The maximum $PM_{2.5}$ concentrations recorded in 2015 occurred in July when the measurements were influenced by the forest fires in northern Manitoba and Saskatchewan. The average $PM_{2.5}$ concentrations measured during 2016 were in the 2 to 5 $\mu g/m^3$ range. The maximum measured values in 2016 are less than the CAAQS (27 µg/m³). The average $PM_{2.5}$ concentration at the MacLellan site for the 105 complete days in 2016 (2.9 µg/m³) was selected as a representative baseline $PM_{2.5}$ concentration in the LAA.

3.3.1.2 PM_{10} Concentrations

The 24-hour PM_{10} measurements at the MacLellan site and Black Sturgeon Reserve are summarized in Table 3-3. There were 56 complete days of PM_{10} measurements (i.e., more than 18 hours in each 24-hour period) at the MacLellan site out of 113 total monitoring days in 2015, and 59 complete days out of 114 total monitoring days in 2016. The average and maximum PM_{10} concentrations for the 56 complete days in 2015 are 15.8 and 103.2 µg/m³, respectively. The average and maximum PM_{10} concentrations for the 59 complete days in 2016 are 4.6 and 11.6 µg/m³, respectively. There are 17 complete days of PM_{10} measurements at Black Sturgeon Reserve out of 19 total monitoring days in 2015; the average and maximum PM_{10} concentrations for these 17 days are 0.8 and 3.1 µg/m³, respectively.

The maximum measured PM_{10} concentrations at the MacLellan site during 2015 are greater than the Manitoba AAQC (50 µg/m³). The maximum PM_{10} concentrations recorded in 2015 occurred during July, when the measurements were influenced by the forest fires in northern Manitoba and Saskatchewan. The average PM_{10} concentrations measured during 2016 were in the 3 to 10 µg/m³ range. The maximum measured values in 2016 are less than Manitoba AAQC (50 µg/m³). The average PM_{10} concentration at the MacLellan site for the 59 complete days in 2016 (4.6 µg/m³) was selected as a representative baseline PM_{10} concentration in the LAA.

Table 3-3 Summary of 24-hour Average $PM_{2.5}$ and PM_{10} Concentrations Measured during the Baseline Program 2015-2016

Year	Parameter	MacLellan Site				Black Sturgeon Reserve			
		Days [a]	Maximum [a] (µg/m³)	Mean [a] (µg/m³)	Median [a] (µg/m³)	Days [a]	Maximum (µg/m³)	Mean (µg/m³)	Median (µg/m³)
2015 [b]	$PM_{2.5}$	67	99.4	11.4	4.1	17	2.3	0.5	0.3
	PM_{10}	56	103.2	15.8	7.1	17	3.1	0.8	0.5
2016	$PM_{2.5}$	105	10.5	**2.9**	2.6	NA	NA	NA	NA
	PM_{10}	59	11.6	**4.6**	4.1	NA	NA	NA	NA

NOTES:
[a] Based on complete days with greater than 18 hours of monitoring data per day
[b] The 2015 measurements are affected by forest fires
NA – not available
Values in **BOLD** text represent the selected representative baseline ambient air concentrations for the LAA.

3.3.1.3 Dustfall

Three dustfall measurements were collected at each dustfall collection site in 2015 and in 2016; the first measurement during June to July, the second measurement during July to August and the third measurement during August to September.

Based on four dustfall collection sites in 2015 and three measurement periods, the average dustfall is 0.51 mg/dm²/day. The overall average and the individual measurements in 2015 are less than the AAQC, 7 g/m²/30-day (2.3 mg/dm²/day).

Based on seven dustfall collection sites in 2016 and three measurement periods, the average dustfall is 0.33 mg/dm²/day. The overall average and the individual measurements in 2016 are less than the AAQC, 7 g/m²/30-day (2.3 mg/dm²/day). The overall average dustfall measured at seven sites in 2016 (0.33 mg/dm²/day or 0.99 g/m²/30-day) was selected as a representative baseline dustfall in the LAA. The dustfall measurements in 2015 were not considered because they were influenced by regional forest fires and thus were not representative of a typical year.

Table 3-4 Summary of Dustfall Measured during the Baseline Program 2015-2016

Station	2015 Total Dustfall (mg/dm²/day)				2016 Total Dustfall (mg/dm²/day)			
	June-July	July-August	August-September	Mean	June-July	July-August	August-September	Mean
01 MacLellan Site	0.72	0.35	0.23	0.43	0.17	0.17	0.38	0.24
02 Lynn Lake	0.79	0.14	0.31	0.41	0.49	<0.10 [a]	0.29	0.29
03 Burge Lake	0.86	1.21	0.24	0.77	0.22	0.13	0.46	0.27
04 Farley Lake	0.94	0.19	0.14	0.42	0.57	0.11	0.26	0.31
06 Cockeram Lake	NA	NA	NA	NA	NA [b]	NA [c]	0.40	0.40
07 Black Sturgeon Reserve Road	NA	NA	NA	NA	0.64	0.73	0.28	0.55
08 Westdal Lake	NA	NA	NA	NA	0.48	0.23	0.14	0.28
Mean Monthly Dustfall	0.83	0.47	0.23	0.51	0.43	0.25	0.32	**0.33**

NOTES:

[a] The July-August result for Lynn Lake was below the detection limit. For the purposes of calculating a conservative overall average, the measured value was assumed to be equal to the detection limit (i.e., 0.10 mg/dm²/day).

[b] No data was collected at Cockeram Lake during June-July as the measurement unit fell over and hence did not collect valid data.

[c] The July-August value for Cockeram Lake was excluded from the results, as large insects contaminated the sample.

NA – not available

Value in **BOLD** text represents the selected representative baseline dustfall for the LAA.

3.3.2 Other Measurements

Local monitoring was complemented with ambient air quality data from other more distant monitoring locations in Manitoba and the Northwest Territories for NO_2, SO_2 and CO. The monitoring networks in Manitoba and the Northwest Territories are part of the National Air Pollution Surveillance (NAPS) program.

MCC operates five continuous air quality monitoring stations in Manitoba: two stations in Winnipeg (Ellen Street and Scotia Street) and one station in each of Brandon, Thompson and Flin Flon (MSD 2019b). The stations are located more than 200 km away from the Project. The closest monitoring stations to the Project are Thompson and Flin Flon, located approximately 230 km to the southeast and 240 km to the southwest of the Project, respectively. Both stations measure SO_2 but not NO_2 and CO. The Winnipeg Ellen Street station measures SO_2, NO_2 and CO. The Thompson station is most affected by industrial emissions from the Vale's mining operations and nickel smelter. Flin Flon is a mining city and copper and zinc mining by Hudson Bay Mining and Smelting is the major source of industrial emissions. However, the copper smelter shut down in June 2010, substantially reducing air emissions in the region. The Winnipeg Ellen Street station in Winnipeg, is located approximately 800 km south of the Project. Winnipeg is the only Census Metropolitan Area in Manitoba with almost 60% of the provincial population. The Winnipeg Ellen Street station is the most influenced by urban and traffic emissions (MSD 2016).

The Northwest Territories Environment and Natural Resources (ENR) operates four continuous ambient air quality monitoring stations in Fort Smith, Inuvik, Norman Wells and Yellowknife (ENR 2019). The Fort Smith station was selected for analysis because it is the southernmost station in the Northwest Territories, experiences similar meteorological conditions, and is in a similar remote location as the Project.

The Wanipigow Sand Extraction Project is in a remote area approximately 160 km northeast of Winnipeg and approximately 700 km southeast of the Project. The Wanipigow Sand Extraction project received its Environment Act Licence No. 3285 from MCC on May 16, 2019. The baseline concentrations from the Wanipigow Sand Extraction Project are largely based on monitoring data from the Winnipeg Ellen Street station except for SO_2 concentrations which are based on monitoring data from the Thompson station. The baseline ambient air concentrations used in that air quality assessment (AECOM 2018) were reviewed and compared with measured concentrations during the baseline monitoring program in 2015 and 2016 and with other historical measurements from Manitoba and the Northwest Territories.

The 90th percentile of hourly measurements for the most recent year (2018) with a complete data record (at least 75% complete) was selected to represent the baseline air quality for each substance of interest. The 90th percentile of measurements is considered adequate to account for uncertainties due the use of distant monitoring stations and the limited number of monitoring stations used for analysis. Baseline concentrations for averaging periods greater than one hour (8-hour, 24-hour, annual) were calculated from the hourly measurements after removing hourly values greater than the 90th percentile. Baseline concentrations based on monitoring data from Manitoba and Northwest Territories, and from the Wanipigow Sand Extraction Project are summarized and compared to the AAQC in Table 3-5.

The baseline ambient air quality concentrations from the monitoring stations in Manitoba and Northwest Territories are less than the Manitoba AAQC. The baseline gaseous concentration levels based on the four monitoring stations and the Wanipigow Sand Extraction Project range from 1% to 18% of Manitoba AAQC with the highest percentages associated with measured NO_2 concentrations at Winnipeg Ellen Street station and the highest SO_2 concentrations measured at Thompson station (Wanipigow Sand Extraction Project). The baseline PM concentrations range from 33% to 73% of the most stringent AAQC with the highest percentages associated with measured PM concentrations at Thompson station and Winnipeg Ellen Street station.

The Fort Smith station measured the lowest ambient concentrations compared to measurements from monitoring stations in Manitoba, except for the SO_2 concentrations, which were lowest at Winnipeg Ellen Street station. The Thompson and Flin Flon monitoring stations are the most influenced by industrial emissions and the Winnipeg Ellen Street station is the most influenced by urban and traffic emissions. The baseline concentrations based on measurements from the Fort Smith station are considered the most representative for the LAA as the station is in a similarly remote area with low population density and with similar meteorological and topographical conditions.

Table 3-5 Baseline Concentrations Derived from Continuous Monitoring Stations in Manitoba and Northwest Territories

Substance	Averaging Period	Baseline Concentration (µg/m³)					Manitoba Ambient Air Quality Criteria (µg/m³) [c]
		Winnipeg Ellen Street[a]	Thompson[a]	Flin Flon[a]	Fort Smith [a]	Wanipigow Sand Extraction Project [b]	
NO_2	1-hour	28.8	NA	NA	**7.5**	29.3	400
	24-hour	25.2	NA	NA	**5.6**	29.3	200
	Annual	10.8	NA	NA	**1.9**	10.9	60
CO	1-hour	696 [d]	NA	NA	**406**	277	15,000
	8-hour	665 [d]	NA	NA	**406**	275	6,000
SO_2	1-hour	2.6	2.6	4.4	**6.0**	23.6 [e]	450
	24-hour	2.6	2.6	4.4	**6.0**	23.6 [e]	150
	Annual	0.36	0.71	2.1	**1.5**	1.81 [e]	30
PM_{10}	24-hour	21.4	29.4	20.3	19.0 [f]	25.6	50
$PM_{2.5}$	24-hour	11.8	13.5	8.8 [g]	12.0	11.7	27
	Annual	5.0	3.9	3.7 [g]	6.4	NA	8.8

NOTES:

[a] Baseline concentration based on monitoring data from 2018 unless noted otherwise and the 90th percentile of hourly measurements. Baseline concentrations for averaging periods greater than one hour (8-hour, 24-hour, annual) are calculated from the hourly measurements after removing values greater than the 90th percentile.

[b] Baseline concentrations from the Wanipigow Sand Extraction Project - Environmental Act Proposal Application (AECOM 2018). Baseline concentration based on monitoring data from Winnipeg Ellen Street station for 2017 unless noted otherwise and the 90th percentile of measured hourly concentrations.

[c] Manitoba Ambient Air Quality Criteria (MSD, 2005) and CAAQS for $PM_{2.5}$

[d] Baseline concentration based on monitoring data from 2016 as the 2017 and 2018 data is less than 75% complete

[e] Baseline concentration based on 2017 monitoring data from Thompson station as the 2017 data from Winnipeg Ellen Street station is less than 75% complete

[f] Baseline concentration based on monitoring data from 2017 as the 2018 data is less than 75% complete

[g] Baseline concentration based on monitoring data from the year with the highest data completeness (2017, 62% complete) out of the three most recent years with data record (2016, 2017 and 2018) as the data completeness for all three years is less than 75%.

NA – not available

Value in **BOLD** text represents the selected representative baseline concentration for the LAA.

3.3.3 Summary of Baseline Ambient Air Quality Concentrations

The representative baseline ambient air concentrations selected for the Project are summarized in Table 3-6 and compared to the applicable AAQC. The baseline PM_{10} and $PM_{2.5}$ concentrations and dustfall were derived from the Project baseline ambient air quality monitoring program in 2016. The baseline TSP concentrations were estimated from the baseline PM_{10} concentration using a correlation proposed by Brooks et al. (1997) which suggests that ambient PM_{10} concentrations comprise approximately 44% of TSP. The 2015 and 2016 baseline monitoring programs did not measure ambient NO_2, SO_2 and CO concentrations because of the remote location of the Project and the absence of nearby industrial activities. The baseline concentrations of NO_2, CO and SO_2 were based on analysis of ambient air monitoring data from the Fort Smith continuous monitoring station in the Northwest Territories. The 90th percentile of hourly measurements from the most recent year with complete data record (2018) was selected to represent the baseline air quality level for each substance of interest. The baseline ambient concentrations of HCN, metals, VOCs and PAHs are assumed negligible because of the remote location of the Project and the absence of industrial activities in the LAA. The baseline metal deposition values were derived from analysis of metals composition in dustfall during the baseline ambient air monitoring program in 2016. The baseline metal deposition values were used in the human health assessment.

Table 3-6 indicates that the selected baseline ambient air concentrations are less than the AAQC. The baseline gaseous concentration levels range from 1.3% to 6.8% of Manitoba AAQC. Baseline PM concentrations and dustfall range from 8.8% to 33% of the most stringent AAQC with the highest percentages associated with ambient $PM_{2.5}$ concentrations. Overall, the existing air quality in the LAA can be characterized as very good.

Table 3-6 Summary of Baseline Ambient Air Quality Concentrations

Substance	Averaging Period	Baseline Concentration (µg/m³)	Manitoba AAQC [a] (µg/m³)	Percent of AAQC (%)
NO_2 [b]	1-hour	7.5	400	1.9
	24-hour	5.6	200	2.8
	Annual	1.9	60	3.2
CO [b]	1-hour	406	15,000	2.7
	8-hour	406	6,000	6.8
SO_2 [b]	1-hour	6.0	450	1.3
	24-hour	6.0	150	4.0
	Annual	1.5	30	5.0
TSP [c]	24-hour	10.5	120	8.8
	Annual	10.5	60	17.5
PM_{10} [d]	24-hour	4.6	50	9.2
$PM_{2.5}$ [d]	24-hour	2.9	27 [e]	10.7
	Annual	2.9	8.8 [e]	33.0

Table 3-6 Summary of Baseline Ambient Air Quality Concentrations

Substance	Averaging Period	Baseline Concentration (µg/m³)	Manitoba AAQC [a] (µg/m³)	Percent of AAQC (%)
Dustfall [d]	30-day	0.99 g/m²	7 g/m² [f]	14.3
	Annual	0.99 g/m²	4.6 g/m² [f]	14.3

3.4 GREENHOUSE GASES

The existing GHG emissions are characterized by summarizing provincial and national inventory totals. The 2017 data (most recently available) for the province and Canada were used (ECCC 2019b).

According to the CEAA 2003 guidance, the Project GHG emissions should be compared to local, provincial, and federal GHG inventories. There are no local GHG emission inventories for the Lynn Lake area; therefore, project GHG emissions cannot be compared to local emissions.

The provincial and national GHG emissions (ECCC 2019c) are presented in Table 3-7. The emissions presented are for the latest year for which data has been published (2017). Manitoba GHG emissions accounted for 3% of the national GHG emissions.

Table 3-7 Provincial and National GHG Emissions (2017)

Parameter	Units	CO_2	CH_4	N_2O	Other GHGs [a] (expressed as CO_{2e})	Total (expressed as CO_{2e})
Manitoba GHG Emissions	kt/y	13,328	3,933	3,910	497	**21,668**
National GHG Emissions	kt/y	571,137	92,862	38,037	13,723	**715,760**
Manitoba contribution to National GHG Emissions	%	2.3%	4.2%	10.3%	3.6%	**3.0%**

NOTE:
[a] Other GHGs include sulphur hexafluoride, hydrofluorocarbons, perfluorocarbons, and nitrogen trifluoride.

4.0 PROJECT AIR EMISSIONS

4.1 EMISSION SOURCES

The sources of air emissions during Project construction and operation are typical for an open pit mine and gold ore processing. Emissions from decommissioning/closure will be similar to those from construction, but lower in magnitude. Project construction and operation will release three types of air emissions:

- Exhaust emissions from construction and mining equipment that include but are not limited to drills, excavators, bulldozers, graders, and haul trucks. The off-road equipment and vehicles consume diesel fuel and the products of combustion are released to the atmosphere. The exhaust emissions contain the by-products of diesel fuel combustion that include oxides of nitrogen (NO_X), sulphur dioxide (SO_2), carbon monoxide (CO), hydrocarbons (HC), DPM, PAHs and metals. DPM is respirable particulate matter that has an aerodynamic diameter less than 10 µm (PM_{10}). It is assumed that 97% of DPM is $PM_{2.5}$ or respirable particulate matter that has an aerodynamic diameter less than 2.5 µm, based on the US EPA NONROAD model documentation (US EPA 2010a).

- Explosives detonation emissions from blasting. Blasting emissions include explosives emissions (NO_X, CO and SO_2) from the detonation of ammonium nitrate fuel oil emulsion explosives.

- Fugitive dust emissions from drilling and blasting, surface disturbance activities, loading and unloading of material, haul roads, access roads and wind erosion result in PM emissions of various size ranges (e.g., TSP, PM_{10} and $PM_{2.5}$) that can also be deposited to off-site ground and water surfaces (i.e., dustfall). TSP includes larger particles, nominally up to 30 µm in diameter. The larger dust particles are removed near the disturbance area by gravitational settling and are the main contributor to dustfall. TSP, PM_{10} and $PM_{2.5}$ emissions are carried off-site by the wind; the smaller $PM_{2.5}$ and PM_{10} fractions tend to be transported further downwind than the TSP.

Additionally, the mill feed storage area and crushing plant, the ore milling and processing plant and the tailings management facility (TMF) at the MacLellan site are associated with the following emissions:

- PM emissions from dust collectors and wet scrubbers at the primary crusher, secondary crusher and the ore milling and processing plant gold room. The crushing plant conveyors and the fine ore stockpile are fully covered and therefore, fugitive dust emissions from these areas are not expected.

- Fugitive hydrogen cyanide (HCN) emissions from the CIP adsorption tanks due to volatilization losses of sodium cyanide (NaCN) used in the leach and adsorption train.

- Fugitive HCN emissions from the TMF pond due to natural degradation and volatilization of a residual amount of cyanide contained in tailings (a maximum of 10 mg/L, by design, of weak acid dissociable cyanide (wad-CN) in wastewater discharged to the TMF) after cyanide detoxification. After gold extraction, the cyanide used in the processing plant is extracted in the cyanide detoxification area before tailings are pumped to the TMF. The wastewater discharge to the TMF after cyanide detoxification treatment might contain up to a maximum of 10 mg/L of wad-CN by design (Ausenco Engineering Canada Inc. [Ausenco] 2019a), which has the potential to volatilize from the TMF pond in the form of gaseous HCN.

The project emission sources during construction and operation are discussed separately for the Gordon site and the MacLellan site in the following sections. Project emissions were estimated using Project description information (Stantec 2017d; Stantec 2017e; Ausenco 2018; Ausenco 2019a; Ausenco 2019b; Q'Pit Inc. 2019) as well as published emission factors.

Predicted ambient concentrations due to Project activities are combined with baseline concentrations, which account for other natural and anthropogenic emission sources not directly included in the dispersion model and are compared to relevant AAQC.

4.2 EMISSION BASES

Since the construction and mining equipment is not used 100% of the time and some construction and mining activities are not constant with time, emission rates are estimated for maximum short-term periods (i.e., hourly emission rates) and for daily average periods (i.e., daily emission rates). The primary mining equipment operates for an average of 15 hours per day and the supporting equipment operates for 8 hours per day (Q'Pit 2019). The maximum hourly emission rates assume that equipment and mining activities occur simultaneously at their maximum intensity for short periods of time (less than 24 hours). Daily average emission rates consider the actual operating hours per day for each equipment and mining activity. The assumptions used to estimate the maximum hourly emission rates and daily average emission rates are provided in Appendix C.

The emissions from mine activities are estimated for three emission bases:

- Hourly Emission Rates—the worst-case maximum emission rates that may occur during any given hour of the mine operation. For the estimation of maximum hourly emissions, a 100% utilization of the mine vehicle fleet is assumed.
- Daily Emission Rates—average daily emission rates considering actual daily mine fleet utilization.
- Annual Emission Rates—average annual emission rates considering actual annual mine fleet utilization.

Maximum hourly emission rates are modelled and compared to short-term AAQC based on averaging periods shorter than 24 hours (e.g., 1-hour, 3-hour, 8-hour). Daily emission rates are assessed against the 24-hour and 30-day AAQC; the annual emission rates are assessed against the annual AAQC.

The hourly, daily and annual emissions rates are expressed in units of grams per second (g/s) for modelling purposes. To illustrate the total emissions for those time intervals (hour, day, year) the emission summaries are presented in kilograms per hour (kg/h) for total hourly emissions, in kilograms per day (kg/d)—for total daily emissions, and in tonnes per year (t/y)—for total annual emissions.

4.3 GORDON SITE

4.3.1 Construction Emissions

The air emissions during construction and pre-production at the Gordon site are associated with the operation of the off-road construction and mining equipment and movement of construction material for the construction of the major components of the Project such as internal haul roads and stockpile pads. Emissions from construction are estimated for the worst-case year of construction that will result in the highest air emissions. The worst-case year of construction is selected based on the greatest intensity of concurrent (simultaneous) construction activities, the highest number of construction equipment units and highest construction material movement. The worst-case construction annual period for emissions from the Gordon site is Q2 Year -2 to Q1 Year -1. The following emissions due to construction activities are estimated for the worst-case construction year:

- Diesel combustion exhaust emissions from construction off-road equipment and haul trucks.
- Diesel combustion exhaust emissions from on-highway trucks and on-road vehicles.
- Fugitive dust and explosives detonation emissions from drilling and blasting.
- Mechanically generated dust by construction off-road equipment movement.
- Fugitive dust emissions from bulldozing and grading.
- Fugitive dust emissions from truck loading and unloading.
- Mechanically generated dust by truck traffic along haul roads and the access road.
- Fugitive dust emissions from wind erosion of stockpiles.

Diesel exhaust emissions from construction off-road equipment are based on the Canadian off-road compression-ignition engine emission standards (ECCC, 2005a). Emissions were conservatively estimated based on Tier 3 emission standards for off-road diesel engines assuming that the majority of the construction fleet will be rented and will include older equipment. Tier 4 emission standards are the most stringent emission standards for new manufactured equipment that came into effect in 2014. The estimated emissions based on Tier 3 standards are therefore conservative. If newer, Tier 4 off-road diesel equipment is used during construction the exhaust emissions would be lower.

Diesel exhaust emissions from on-highway trucks and other on-road vehicles travelling on the access road were estimated using emission factors for on-road vehicles derived using the US EPA Motor Vehicle Emission Simulator model version 2014a (MOVES2014a; US EPA 2015). Since MOVES2014a was originally developed for the United States, a surrogate US county and state (Hill County, Montana) was selected to represent the Project in terms of local meteorological conditions and vehicle populations. The model was run for a rural unrestricted road type that best represents the access road, for year 2018 to represent current vehicle populations and age distributions, separately for winter and summer, and with fuel formulations specific to Manitoba and Canada. Diesel exhaust emissions were estimated using the MOVES2014a emission factors in grams per vehicle-mile travelled (g/VMT) for each vehicle type, the number of vehicles round trips per day and the length of the road.

Blasting emissions include fugitive dust generated from the blast and explosives emissions (NO_X, CO and SO_2) from the detonation of ammonium nitrate fuel oil emulsion explosives.

Blasting emissions and fugitive dust emissions from construction activities and wind erosion were estimated using emission factors from various chapters of the US EPA AP-42 Fifth Edition Compilation of Air Pollutant Emission Factors (US EPA 1995a). A detailed description of construction emission calculations is provided in Appendix C.

A summary of annual emissions during the worst-case year of construction (Q2 Year -2 to Q1 Year -1) at Gordon site is provided in Table 4-1. Total annual emissions during construction are less than the annual emissions during operation (Table 4-4). The data in Table 4-1 indicate that, on an annual basis:

- Emissions of gaseous CACs (NO_X, CO, SO_2, DPM and VOC) during construction are 65% to 85% less than the corresponding annual emission totals during operation. The highest difference (85%) corresponds to NO_X emissions. The lower gaseous CAC emissions during construction are due to less off-road equipment units and less blasting activities during construction and pre-production, and no ore transported from Gordon site to the MacLellan site ore milling and processing plant during construction.
- Fugitive particulate matter emissions (TSP, PM_{10} and $PM_{2.5}$) during construction are 70% to 76% less than the corresponding annual emission totals during operation. The highest difference (76%) corresponds to PM_{10} and $PM_{2.5}$ emissions. The lower fugitive PM emissions during construction are due to less truck traffic along the haul roads and access road, less off-road equipment units and equipment movement at the site and no haul trucks transporting ore from Gordon site to the MacLellan site ore milling and processing plant during construction and pre-production.

4.3.2 Operation Emissions

Emissions during operation at the Gordon site are associated with diesel combustion exhaust from the mining equipment and fugitive dust emissions generated from mining activities and wind erosion. The Gordon site emissions include emissions associated with ROM ore haulage on PR 391. Emissions from operation are estimated for the worst-case year of mine operation that will result in the highest air emissions. The worst-case year is selected based on highest production rate, highest anticipated number of mining equipment units and highest anticipated material movement. The worst-case year for emissions from the Gordon site and ROM ore haulage on PR 391 is Year 2 of operation. The following emissions due to mining activities are estimated for Year 2:

- Diesel combustion exhaust emissions from mining off-road equipment and haul trucks.
- Diesel combustion exhaust emissions from on-highway trucks and on-road vehicles.
- Diesel combustion emissions from a permanent diesel generator.

- Fugitive dust and explosives detonation emissions from drilling and blasting.
- Mechanically generated dust by mining off-road equipment movement.
- Fugitive dust emissions from bulldozing and grading.
- Fugitive dust emissions from truck loading and unloading.
- Mechanically generated dust by truck traffic along haul roads and the access road.
- Mechanically generated dust by truck traffic along PR 391.
- Fugitive dust emissions from wind erosion of stockpiles.

Diesel exhaust emissions from mining off-road equipment are based on the Canadian off-road compression-ignition engine emission standards (ECCC 2005a). The Proponent will procure new mining equipment that complies with Tier 4 standards for off-road diesel engines and therefore, emissions were based on the Tier 4 standards. Emission speciation profiles for VOCs, PAHs and metals for off-road diesel equipment were derived using the US EPA MOVES model (MOVES2014a; US EPA 2015) and the integrated NONROAD2008 model. The MOVES2014a-NONROAD model uses a compilation of equipment of different ages up to the year that is modelled. Emissions were estimated for year 2018 to represent mining equipment that complies with Tier 4 emission standards for off-road diesel engines.

Diesel exhaust emissions from on-highway trucks and other on-road vehicles travelling on the access road and PR 391 were estimated using emission factors for on-road vehicles derived from the MOVES2014a model (US EPA 2015). The model was run for a rural unrestricted road type that best represents the access road and PR 391, for year 2018 to represent current vehicle populations and age distributions, separately for winter and summer, and with fuel formulations specific to Manitoba and Canada. Diesel exhaust emissions were estimated using the MOVES2014a emission factors in g/VMT for each vehicle type, the number of vehicles round trips per day and the length of the road.

A permanent diesel generator will provide power to the facilities at the Gordon site. Diesel exhaust emissions from the generator are based on manufacturer specifications. The diesel generator complies with Tier 3 emission standards for off-road diesel engines.

Blasting emissions and fugitive dust emissions from mining activities and wind erosion were estimated using emission factors from various chapters of the US EPA AP-42 Fifth Edition Compilation of Air Pollutant Emission Factors emission factors (US EPA 1995a). Emission speciation profiles for metals in fugitive dust are based on laboratory analysis of mine rock, ore, overburden and tailings samples collected during the geochemistry baseline program in 2015 and 2016. Details of the geochemistry baseline program are provided in the Geochemistry Baseline TDR (Stantec 2017c) and associated Validation TDR (Stantec 2020c). A detailed description of emission calculations is provided in Appendix C.

Summaries of hourly, daily and annual emission rates during the worst-case year of operation (Year 2) at the Gordon site and PR 391 are provided in Table 4-2, Table 4-3 and Table 4-4, respectively. The NO_X, CO, SO_2, DPM and VOC emissions are associated with combustion sources only. The maximum hourly emission rates assume that all equipment and mining activities occur simultaneously at their maximum intensity for short periods of time, while daily average emission rates consider the actual operating hours per day for each equipment and mining activity. The daily equivalent emissions rates are about 48% of the maximum hourly emission rates. Table 4-3 indicates that, on a daily basis:

- Most of the SO_2 emissions are associated with explosives detonation.
- Most of the NO_X, CO and DPM emissions are associated with mining off-road equipment exhaust and haul trucks on PR 391.
- Most of the VOC emissions are associated with mining off-road equipment exhaust.
- Most of the fugitive TSP, PM_{10} and $PM_{2.5}$ emissions are associated with the fugitive haul road dust emissions and fugitive dust generated by mining off-road equipment movement.

4.4 MACLELLAN SITE

4.4.1 Construction Emissions

Emissions during construction and pre-production at the MacLellan site are associated with the operation of the off-road construction and mining equipment, and movement of construction material for the construction of the major components of the Project such as internal haul roads, stockpile pads, processing plant infrastructure and the TMF. The emissions from construction are estimated for the worst-case year of construction that will result in the highest air emissions. The worst-case year of construction is selected based on the peak in the concurrent construction activities, the highest anticipated number of construction equipment units and highest anticipated construction material movement. The worst-case construction annual period for emissions from the MacLellan site is Q2 Year -2 to Q1 Year -1. The following emissions due to construction activities are estimated for the worst-case construction year:

- Diesel combustion exhaust emissions from construction off-road equipment and haul trucks.
- Diesel combustion exhaust emissions from on-highway trucks and on-road vehicles.
- Fugitive dust and explosives detonation emissions from drilling and blasting.
- Diesel combustion exhaust emissions and fugitive dust emissions from a mobile crushing plant.
- Mechanically generated dust by construction off-road equipment movement.
- Fugitive dust emissions from bulldozing and grading.
- Fugitive dust emissions from truck loading and unloading.

Table 4-1 Annual Emission Rates during Construction at Gordon Site (Q2 Year -2 to Q1 Year -1)

Emission Source	Annual Emission Rates [a] (t/y)									
	NO_X	CO	SO_2	DTSP	DPM_{10}	$DPM_{2.5}$	FTSP	FPM_{10}	$FPM_{2.5}$	VOC
Diesel Exhaust Emissions from Construction Off-Road Equipment	15.2	36.5	0.069	0.585	0.585	0.568	-	-	-	2.36
Diesel Exhaust Emissions from On-Highway Trucks and On-Road Vehicles	0.735	0.350	0.002	0.062	0.062	0.037	-	-	-	0.085
Drilling and Blasting [b]	11.2	47.6	1.40	-	-	-	5.43	2.83	0.841	-
Fugitive Dust Emissions from Construction Off-Road Equipment Movement	-	-	-	-	-	-	316	90.1	9.01	-
Fugitive Dust Emissions from Bulldozing and Grading	-	-	-	-	-	-	51.3	13.3	2.71	-
Fugitive Dust Emissions from Truck Loading and Unloading	-	-	-	-	-	-	5.09	2.41	0.365	-
Fugitive Dust Emissions from Haul Roads and Access Road [c]	-	-	-	-	-	-	147	41.8	4.18	-
Fugitive Dust Emissions from PR 391	-	-	-	-	-	-	5.07	1.01	0.249	-
Wind Erosion of Stockpiles [d]	-	-	-	-	-	-	0	0	0	-
Total Emissions	27.2	84.5	1.47	0.648	0.648	0.605	530	151	17.4	2.44

NOTES:

[a] Annual average emission rates based on the actual hours of operation per day for each construction activity

[b] Drilling occurs 5.3 hours per day and blasting occurs for 1 hour every 3 days.

[c] Fugitive dust emission rates for haul roads and the access road include 75% dust control efficiency due to water application in summer and 90% natural mitigation efficiency in winter. Summer is assumed six months, May to October.

[d] Wind erosion emissions represent emissions at hourly average wind speed greater than 16.4 m/s. At wind speeds less than 16.4 m/s, no wind erosion emissions are generated based on US EPA emission factor for wind erosion of overburden (US EPA 2006, Appendix C).

DTSP, DPM_{10}, $DPM_{2.5}$ – diesel particulate matter of different particle size ranges; FTSP, FPM_{10}, $FPM_{2.5}$ – fugitive particulate matter of different particle size ranges

"-" not applicable

- Mechanically generated dust by truck traffic along haul roads and the access roads.
- Fugitive dust emissions from wind erosion of stockpiles.

Diesel exhaust emissions from construction off-road equipment are based on the Canadian off-road compression-ignition engine emission standards (ECCC 2005a). Emissions were conservatively estimated based on Tier 3 emission standards for off-road diesel engines assuming that the majority of the construction fleet will be rented and will include older equipment. The estimated emissions based on Tier 3 standard are therefore conservative. If newer, Tier 4 off-road diesel equipment is used during construction the exhaust emissions would be lower.

Diesel exhaust emissions from on-highway trucks and other on-road vehicles travelling on the access roads were estimated using emission factors for on-road vehicles derived from the MOVES2014a model (US EPA 2015). The model was run for a rural unrestricted road type that represents the access roads, for 2018 to represent current vehicle populations and age distributions, separately for winter and summer, and with fuel formulations specific to Manitoba and Canada. Diesel exhaust emissions were estimated using the MOVES2014a emission factors in g/VMT for each vehicle type, the number of vehicles round trips per day and the length of the road.

Blasting emissions and fugitive dust emissions from construction activities and wind erosion were estimated using emission factors from various chapters of the US EPA AP-42 Fifth Edition Compilation of Air Pollutant Emission Factors (US EPA 1995a). A detailed description of construction emission calculations is provided in Appendix C.

A summary of annual emissions during the worst-case year of construction at the MacLellan site is provided in Table 4-5. Total annual emissions during construction are less than the annual emissions during operation (Table 4-8). The data in Table 4-5 indicate that, on an annual basis:

- Emissions of gaseous CACs (NO_X, CO, SO_2 and VOC) during construction are 39% to 65% less than the corresponding annual emission totals during operation. The highest difference (65%) corresponds to NO_X emissions. The lower gaseous CAC emissions during construction are due to less off-road equipment units and less blasting activities during construction and pre-production.
- Emissions of DPM are approximately 20% higher than the corresponding annual emissions totals during operation. The higher DPM emissions during construction are due to the conservative assumption that construction off-road equipment will be mostly rented and will comply with older (Tier 3) Canadian emission standards for off-road diesel engines (ECCC 2005a). If newer (Tier 4) construction off-road equipment is used the DPM emissions during construction will be less. During operation, the Proponent will procure new mining equipment that complies with Tier 4 standards. The Tier 3 DPM emission standards are 5 to 20 times higher than the corresponding Tier 4 standards for engine power ranging from 75 hp to greater than 750 hp. For comparison, the Tier 3 NO_X emission standards are 1.7 to 11 times higher than the corresponding Tier 4 standards, for the same engine power range.
- Fugitive particulate matter emissions (TSP, PM_{10} and $PM_{2.5}$) during construction are 20% to 41% less than the corresponding annual emission totals during operation. The highest difference (41%)

corresponds to PM_{10} emissions. The lower fugitive PM emissions during construction are due to less truck traffic along the haul roads and access roads, and less off-road equipment units and equipment movement at the site during construction and pre-production.

4.4.2 Operation Emissions

Emissions during operation at the MacLellan site are associated with diesel combustion exhaust from the mining equipment, fugitive dust emissions generated from mining activities and wind erosion, fugitive dust emissions from the mill feed storage area and crushing plant, emissions from the ore milling and processing plant and the TMF. Emissions from operation are estimated for the worst-case year of mine operation that will result in the highest air emissions. The worst-case year is selected based on highest anticipated production rate, largest number of mining equipment units and highest material movement. The worst-case year for emissions from the MacLellan site is Year 7 of operation. The following emissions due to mining activities are estimated for Year 7:

- Diesel combustion exhaust emissions from mining off-road equipment and haul trucks.
- Diesel combustion exhaust emissions from on-highway trucks and on-road vehicles.
- Fugitive dust and explosives detonation emissions from drilling and blasting.
- Mechanically generated dust by mining off-road equipment movement.
- Fugitive dust emissions from bulldozing and grading.
- Fugitive dust emissions from truck loading and unloading.
- Mechanically generated dust by truck traffic along haul roads and the access roads.
- Fugitive dust emissions from wind erosion of stockpiles.
- PM emissions from the primary and secondary crushers.
- PM emissions from dust collectors at the ore milling and processing plant gold room.
- Fugitive dust emissions from wind erosion of the TMF dry banks.
- Fugitive HCN emissions from the processing plant leach and adsorption tanks.
- Fugitive HCN emissions from the TMF pond.

Diesel exhaust emissions from mining off-road equipment are based on the Canadian off-road compression-ignition engine emission standards (ECCC 2005a). The Proponent will procure new mining equipment that complies with Tier 4 standards and therefore, emissions are based on the Tier 4 standards. Emission speciation profiles for VOCs, PAHs and metals for off-road diesel equipment were derived using the US EPA MOVES model (MOVES2014a; US EPA, 2015) and the integrated NONROAD2008 model.

Emissions were estimated for year 2018 to represent mining equipment that complies with Tier 4 emission standards for off-road diesel engines.

Diesel exhaust emissions from on-highway trucks and other on-road vehicles travelling on the access roads were estimated using emission factors for on-road vehicles derived from the MOVES2014a model (US EPA 2015). The model was run for a rural unrestricted road type that best represents the access roads, for year 2018 to represent current vehicle populations and age distributions, separately for winter and summer, and with fuel formulations specific to Manitoba and Canada. Diesel exhaust emissions were estimated using the MOVES2014a emission factors in g/VMT for each vehicle type, the number of vehicles round trips per day and the length of the road.

Blasting and fugitive dust emissions from mining activities and wind erosion were estimated using emission factors from various chapters of the US EPA AP-42 Fifth Edition Compilation of Air Pollutant Emission Factors (US EPA 1995a). Emission speciation profiles for metals in fugitive dust are based on laboratory analysis of mine rock, ore, overburden and tailings samples collected during the geochemistry baseline program in 2015 and 2016. Details of the geochemistry baseline program are provided in the Geochemistry Baseline TDR (Stantec 2017c) and associated Validation TDR (Stantec 2020c).

PM emissions occur from the primary crusher dust collector, the secondary crusher wet scrubber and the dust collectors at the processing plant gold room. PM emissions from the dust collectors and the wet scrubber were estimated based on the dust loading (g/m^3), exhaust flow rate and the dust collection efficiency provided by Ausenco (2017).

Fugitive HCN emissions result from volatilization of sodium cyanide used in the processing plant leach and adsorption tanks, and from residual cyanide (after cyanide detoxification) in the TMF pond. HCN emissions from the processing plant and the TMF were estimated following the Australian Emission Manual for Gold Ore Processing (Australian Government 2006). A detailed description of emission calculations is provided in Appendix C.

Summaries of hourly, daily and annual emission rates during the worst-case year of operation (Year 7) at the MacLellan site are provided in Table 4-6, Table 4-7 and Table 4-8, respectively. The NO_X, CO, SO_2, DPM and VOC emissions are associated with combustion sources only. The maximum hourly emission rates assume that all equipment and mining activities occur simultaneously at their maximum intensity for short periods of time, while daily average emission rates consider the actual operating hours per day for each equipment and mining activity. The daily equivalent emissions rates are about 58% of the maximum hourly emission rates. Table 4-7 shows that, on a daily basis:

- Most of the SO_2 emissions are associated with explosives detonation.
- Most of the NO_X, CO and DPM emissions are associated with mining off-road equipment exhaust.
- Most of the VOC emissions are associated with mining off-road equipment exhaust.
- Most of the fugitive TSP, PM_{10} and $PM_{2.5}$ emissions are associated with the fugitive haul road dust emissions and fugitive dust generated by mining off-road equipment movement.

Table 4-5 Annual Emission Rates during Construction at MacLellan Site (Q2 Year -2 to Q1 Year -1)

Emission Source	Annual Emission Rates [a] (t/y)

- HCN emissions from the TMF are about twice the emissions from the processing plant.

5.0 PROJECT GHG EMISSIONS

The substantive sources of greenhouse (GHG) emissions during construction and operation are the mobile and stationary equipment exhausts, blasting using an ammonium nitrate fuel oil emulsion explosive and land clearing . These GHG emissions consist primarily of carbon dioxide (CO_2), with smaller amounts of methane (CH_4) and nitrous oxide (N_2O). Per the GHG Protocol (WRI 2013), the GHG emissions include direct emissions from the Project during construction and operation (i.e., Scope 1) as well as indirect emissions associated with the consumption of purchased electricity (Scope 2). Other indirect GHG emissions associated with upstream sources such as production of purchased materials and upstream transportation and distribution (i.e., Scope 3) are assumed to be negligible compared to direct Project GHG emissions. Therefore, the Scope 3 GHG emissions are not evaluated for this assessment and also it is an optional reporting category as per GHG Protocol (WRI 2013).

The US EPA NONROAD model (US EPA 2010a) was used to estimate the fuel consumption of construction and mining off-road equipment based on input information such as engine type, number of units, power rating, utilization factors and total operating hours. Diesel combustion emission factors from the ECCC National Inventory Report (ECCC 2019c) were used to estimate emissions from the construction and mining equipment and fuel consumption rates.

Diesel exhaust GHG emission factors for on-highway trucks transporting ore from the Gordon site to the MacLellan site ore milling and processing plant and on-highway trucks carrying fuel, explosives and consumables for the ore milling and processing plant and other on-road vehicles travelling on the access roads and PR 391 were derived from the US EPA MOVES model (MOVES2014a; US EPA 2015). The model was run for a rural unrestricted road type that best represents the access roads and PR 391, for year 2018 to represent current vehicle populations and age distributions, separately for winter and summer and with fuel formulations specific to Manitoba and Canada. Diesel exhaust emissions for on-road vehicles were estimated using the MOVES emission factors (g/VMT), the number of vehicles round trips per day and the length of the road.

The GHG emissions from explosives detonation were estimated using an emission factor (0.189 t CO_2/tonnes explosives) recommended by the Mining Association of Canada (2014).

The GHG emissions from land clearing were estimated using Manitoba-specific emission factors derived by Natural Resources Canada for deforestation activities in Manitoba (NRCan 2017) as part of the 2017 National Inventory Report (ECCC 2017). Emission factors were derived for four terrestrial ecozones in Manitoba. Based on the location of the Project, the emission factor for Boreal Shield West was used. The GHG emissions from land clearing were estimated from the emission factor for salvage uprooting and burn (85.6 t CO_{2e}/ha) and the area of land clearing (861 ha within MacLellan site and 187 ha within Gordon site) during the Project construction phase. The GHG emissions from land clearing were divided by the two years of Project construction to estimate an annual GHG emission contribution. This annual estimate does not include GHG emissions from decay of biomass after the land clearing activities assuming that merchantable timber will be transported out of the PDA and other cleared biomass will be open burnt.

Indirect GHG emissions are associated with electricity consumption at the MacLellan site. Electrical power for the Gordon site will be provided by on-site diesel generators. The indirect GHG emissions from electricity consumption at MacLellan site were calculated using the electricity consumption emission factor for Manitoba (2.1 g CO_{2e}/kWh) from the ECCC National Inventory Report (ECCC 2019c) and the estimated electricity usage at the MacLellan site during operation (16,900 kWh).

5.1 GORDON SITE

5.1.1 Construction Emissions

The maximum annual GHG emissions from the Gordon site construction are presented in Table 5-1. The Gordon site construction GHG emissions include emissions from heavy off-road equipment, on-highway trucks and vehicles, the stationary generator, blasting and land clearing. Approximately 16.0 kt CO_{2e} are estimated to be released during the worst-case year of construction (Q2 Year -2 to Q1 Year -1). Conservatively assuming continuous release of the worst-case year GHG emissions over the construction period (two years), the total GHG emissions during construction are estimated to be 32.0 kt CO_{2e}. On an annual basis, the Gordon site construction contributes approximately 0.074% and 0.002% to provincial and national GHG emission totals, respectively.

Table 5-1 Estimated GHG Emissions from Gordon Site Construction

Parameter	Units	CO_2	CH_4	N_2O	Total (expressed as CO_{2e})
Construction GHG Emissions	kt/y	15.8	0.0002	0.0006	**16.0**
Manitoba GHG Emissions [a]	kt/y	13,328	3,933	3,910	**21,668 [b]**

Project construction contribution to national GHG Emissions	%	0.003%	0.0000002%	0.0000016%	**0.002%**

NOTE:
[a] Provincial and national GHG emission totals from ECCC NIR (ECCC 2019c)
[b] Provincial and national GHG emission totals include other fluorinated GHGs

5.1.2 Operation Emissions

The maximum annual GHG emissions from Gordon site operation are presented in Table 5-2. The Gordon site operation GHG emissions include emissions from heavy off-road equipment, on-highway trucks and vehicles, a diesel-fired electrical generator and blasting. Approximately 36.5 kt CO_{2e} are estimated to be released during the worst-case year of operation and corresponding ore haulage on PR 391 (Year 2).

Conservatively assuming continuous release of the worst-case year GHG emissions over the operational period (five years), the total GHG emissions during operation are estimated to be 183 kt CO_{2e}. On an annual basis, the Gordon site operation contributes approximately 0.17% and 0.005% to the provincial and national GHG emission totals, respectively.

Table 5-2 Estimated GHG Emissions from Gordon Site Operation

Parameter	Units	CO_2	CH_4	N_2O	Total (expressed as CO_{2e})
Operation GHG Emissions	kt/y	35.8	0.0009	0.0025	**36.5**
Manitoba GHG Emissions [a]	kt/y	13,328	3,933	3,910	**21,668** [b]
National GHG Emissions [a]	kt/y	571,137	92,862	38,037	**715,760** [b]
Project operation contribution to Manitoba GHG Emissions	%	0.27%	0.00002%	0.00006%	**0.17%**
Project operation contribution to national GHG Emissions	%	0.006%	0.000001%	0.000007%	**0.005%**

NOTE:
[a] Provincial and national GHG emission totals from ECCC NIR (ECCC 2019c)
[b] Provincial and national GHG emission totals include other fluorinated GHGs

5.2 MACLELLAN SITE

5.2.1 Construction Emissions

The maximum annual GHG emissions from the MacLellan site construction are presented in Table 5-3. The MacLellan site construction GHG emissions include emissions from heavy off-road equipment, on-highway trucks and vehicles, blasting and land clearing. Approximately 64.6 kt CO_{2e} are estimated to be released during the worst-case year of construction (Q2 Year -2 to Q1 Year -1). Conservatively assuming continuous release of the worst-case year GHG emissions over the construction period (two years), the total GHG emissions during construction are estimated to be 129 kt CO_{2e}. On an annual basis, the MacLellan site construction contributes approximately 0.30% and 0.009% to provincial and national GHG emission totals, respectively.

Table 5-3 Estimated GHG Emissions from MacLellan Site Construction

Parameter	Units	CO_2	CH_4	N_2O	Total (expressed as CO_{2e})
Construction GHG Emissions	kt/y	63.9	0.0007	0.0022	**64.6**
Manitoba GHG Emissions [a]	kt/y	13,328	3,933	3,910	**21,668 [b]**
National GHG Emissions [a]	kt/y	571,137	92,862	38,037	**715,760 [b]**
Project construction contribution to Manitoba GHG Emissions	%	0.48%	0.00002%	0.00006%	**0.30%**
Project construction contribution to National GHG Emissions	%	0.011%	0.000001%	0.000006%	**0.009%**

NOTE:
[a] Provincial and national GHG emission totals from ECCC NIR (ECCC 2019c)
[b] Provincial and national GHG emission totals include other fluorinated GHGs

5.2.2 Operation Emissions

The maximum annual GHG emissions from the MacLellan site operation are presented in Table 5-4. The MacLellan site operation GHG emissions include emissions from heavy off-road equipment, on-highway trucks and vehicles and blasting. Approximately 68.0 kt CO_{2e} are estimated to be released during the worst-case year of operation (Year 7). Conservatively assuming continuous release of the worst-case year GHG emissions over the operation period (13 years), the total GHG emissions during operation are estimated to be 884 kt CO_{2e}. On an annual basis, the MacLellan site operation contributes approximately 0.31% and 0.01% to the provincial and national emission totals, respectively.

The estimated total indirect GHG emissions from electricity consumption at the MacLellan site during operation is 0.311 kt CO_{2e}/year, which is less than 1% of the total direct annual GHG emissions (68 kt CO_{2e}/year). These GHG emissions are included into the annual GHG emissions totals for the Project in Table 5-4 Other indirect GHG emissions (i.e., Scope 3) are not accounted into the annual GHG emissions totals for the Project as they are assumed to be negligible compared to direct Project GHG emissions. Therefore, the Scope 3 GHG emissions are not evaluated for this assessment and also it is an optional reporting category as per GHG Protocol (WRI 2013).

Table 5-4 Estimated GHG Emissions from MacLellan Site Operation

Parameter	Units	CO_2	CH_4	N_2O	Total (expressed as CO_{2e})
Operation GHG Emissions	kt/y	66.7	0.0018	0.0055	**68.3**
Manitoba GHG Emissions [a]	kt/y	13,328	3,933	3,910	**21,668** [b]
National GHG Emissions [a]	kt/y	571,137	92,862	38,037	**715,760** [b]
Project operation contribution to Manitoba GHG Emissions	%	0.50%	0.00005%	0.00014%	**0.32%**

[b] Provincial and national GHG emission totals include other fluorinated GHGs

6.0 ENVIRONMENTAL CONTROL AND MANAGEMENT PROCEDURES

Mitigation measures will be implemented to manage and reduce Project emissions during construction and operation. Ambient air quality and meteorology monitoring will be implemented to provide an understanding of meteorological conditions and off-site ambient concentrations, and to determine the need for additional mitigation. The monitoring systems will include the installation and operation of a meteorological tower (wind speed and wind direction, air temperature and relative humidity, total precipitation) and particulate matter (TSP, PM_{10}, $PM_{2.5}$) monitoring equipment. Based on the current wind conditions and measured ambient concentration levels, appropriate and effective mitigation options will be implemented to reduce Project emissions. This emissions mitigation management is referred to as “adaptive management”.

The mitigation measures associated with ambient air quality to reduce combustion emissions are also applicable to the mitigation of GHG emissions because combustion sources account for virtually all the GHG emissions associated with the Project construction and operation.

6.1 MITIGATION BY PROJECT DESIGN

Mitigation measures to reduce air and GHG emissions that are incorporated in the Project design include:

- Enclosure of the mill feed storage area and crushing plant conveyors and the fine ore stockpile to reduce fugitive dust emissions. PM emissions from the enclosed conveyors and fine ore stockpile are assumed negligible.
- Use of dust collection/control systems (e.g., baghouse) at the primary crusher and the processing plant gold room to reduce PM emissions. Use of a wet scrubber at the secondary crusher. The dust collection

efficiencies of the dust collectors and wet scrubber are considered in the calculation for the PM emissions.

- Optimization of haul roads and infrastructure to reduce transportation and haul distances.
- Optimization of the TMF to reduce the area of exposed dry surfaces to reduce the potential for windblown dust emissions.
- Enclosed leaching and adsorption processes at the ore milling and processing plant to reduce fugitive HCN emissions due to volatilization loses.
- Limited concentration of wad-cyanide (after cyanide detoxification) in water discharge to the TMF to 10 mg/L to reduce potential fugitive HCN emissions from the TMF pond surface.

6.2 BEST MANAGEMENT PRACTICES

Emission mitigation measures during Project construction and operation are based on standard BMPs for the reduction of air emissions from construction activities (ECCC 2005b) and mining activities (CEMI 2010).

The following BMPs will be implemented for the management and reduction of diesel exhaust emissions and associated air contaminants and GHGs from off-road equipment and vehicles during construction and operation at the Gordon and MacLellan sites:

- Engines and exhaust systems will be properly maintained to keep construction and mining equipment in good working condition.
- The concentration of sulphur in diesel fuel shall not exceed 15 mg/kg, as per the Sulphur in Diesel Fuel Regulations (SOR/2002-254 last amended on 2017-06-02; ECCC 2002) that came into effect in 2006 for on-road vehicles and in 2010 for off-road equipment. This sulphur concentration is used in the emissions quantification for the Project.
- Haul trucks and vehicle idling times will be reduced to the extent possible.
- Cold starts will be limited to the extent possible.

The following BMPs will be implemented for the management and reduction of fugitive dust emissions from construction and mining activities at the Gordon and MacLellan sites:

- On-site haul roads and access roads will be maintained in good condition, with regular inspections to monitor loose dust on the roads to reduce dust “track out” onto public roads.
- During dry periods, water will be applied to haul roads and access roads to reduce dust emissions. The application of water will be limited to non-freezing temperatures to avoid icing that can present a safety hazard. Watering is most effective immediately after application, and repeated watering several times

a day might be required, depending on the surface and meteorological conditions. A 75% control efficiency due to watering is applied to the quantified PM emissions from haul roads and access roads for the Project based on the Western Regional Air Partnership (WRAP) Fugitive Dust Handbook (WRAP 2006).

- Chemical dust suppressants will be applied to haul roads as an alternative option to watering. While chemical dust suppressants can be more effective at controlling fugitive dust than watering, they are also more expensive. Therefore, chemical dust suppression will be applied on an as-needed basis during high wind conditions or if measured ambient PM concentrations are in exceedance of the Manitoba AAQC and if an increase of watering is determined ineffective or unfeasible at the time. Examples of suppressants include chlorides, petroleum products, liquid polymer emulsions, and agglomerating chemicals. These suppressants, if required, will be applied, as per the manufacturer's recommendations, to preclude unintended environmental effects.
- Haul truck speed on the on-site haul roads will be limited to 35 km/h (loaded) and 40 km/h (empty). Vehicle speed on the access roads will be limited to 40 km/h.
- Track-out of material to PR 391 will be reduced by dust sweeping and truck wheel washing stations prior to entering onto PR 391.
- Surfaces of topsoil and overburden stockpiles will be stabilized during extended periods between usage, by means of vegetating or covering the exposed surfaces.

Additional mitigation measures can be implemented on an as-required basis.

6.3 AIR QUALITY MONITORING AND ADAPTIVE MANAGEMENT

An Air Quality Management Plan (AQMP) will be created for Project construction and operation. The AQMP will specify the mitigation measures for the management and reduction of air emissions during Project construction and operation, the ambient air quality and meteorology monitoring program and the reporting requirements of monitoring results to Manitoba Conservation and Climate.

Ambient air quality and meteorology monitoring will include:

- Meteorological monitoring (wind speed and wind direction, air temperature and relative humidity, rain precipitation, snow depth).
- Ambient PM monitoring (TSP, PM_{10} and $PM_{2.5}$).

The results of the ambient PM monitoring will be used to assess the effectiveness of the dust mitigation measures and to evaluate the need for more rigorous dust mitigation.

For example, if the monitoring program indicates that ground-level TSP, PM_{10} and/or $PM_{2.5}$ concentrations are greater than the Manitoba AAQC, additional mitigation measures to reduce PM emissions will be implemented. Given that dust from the haul roads is the largest source of particulate emissions, more frequent road watering or an application of a dust suppressant could be implemented.

6.4 GREENHOUSE GAS MANAGEMENT PLAN

The purpose of the Greenhouse Gas Management Plan (GHGMP) will be to manage Project greenhouse gas (GHG) emissions in accordance with relevant GHG emissions management legislation. The GHGMP will also include policy updates, emission source descriptions, data management framework, effectiveness of mitigation, follow-up and monitoring for GHGs, based on provincial and federal reporting requirements.

7.0 ASSESSMENT APPROACH

The effects of Project emissions on ambient air quality are evaluated by using a numerical atmospheric dispersion model. Atmospheric dispersion models simulate the transport, dispersion, transformation, and deposition of emissions in the atmosphere. Dispersion models are used to predict ambient concentrations for a wide range of meteorological conditions and account for terrain influences.

7.1 SELECTED MODELS

For this assessment, the CALMET/CALPUFF® model system (Scire et al. 2000a; 2000b; 2011) was used to determine the effect of Project operation emissions on ambient air quality. The most recent model versions available at the time of the assessment were used:

- CALMET® version 6.5.0 (level 150223) – a diagnostic three-dimensional meteorological model.
- CALPUFF® version 7.2.1 (level 150618) – a numerical atmospheric dispersion model.

The modelling system was applied in accordance with the draft Guidelines for Air Dispersion Modelling in Manitoba (Manitoba Conservation, 2006) and in the absence of specific requirements in the Manitoba Guidelines, the modelling approach followed guidance from the ADMG for Ontario (MOECC 2016) and the Alberta Air Quality Model Guideline (AEP 2013).

The proposed dispersion modelling approach was described in an air quality dispersion modelling plan (Stantec 2017d), which was prepared for review by MCC and ECCC. Following submission, feedback was provided by MCC and incorporated in the air quality assessment by Stantec. In 2019, after minor changes to the layout of Project infrastructure and the corresponding letter to the Canadian Environmental Assessment Agency (now Impact Assessment Agency of Canada [IAAC]; Stantec 2019), the dispersion modelling plan was resubmitted for review and confirmation by MCC and ECCC. Following resubmission, additional feedback was provided by MCC and ECCC and incorporated in the air quality assessment by Stantec. The MCC and ECCC approved the air quality dispersion modelling plan on August 13, 2019 (MSD 2019c; ECCC 2019a). The air quality dispersion modelling plan (Stantec 2017e) and Stantec responses to MCC and ECCC comments (Stantec 2019) are provided in Appendix B.

7.2 CALMET METEOROLOGICAL MODEL

The CALMET® model (Scire et al. 2000a) was used to provide three-dimensional hourly meteorological data (winds, temperatures and turbulence) for a five-year period (2012-2016) required for the CALPUFF® transport, dispersion, and deposition model. The CALMET® model domain of 70 km by 48 km contains the LAA (50 km by 28 km) with a buffer of 10 km on each side to minimize potential computational boundary effects near the perimeter of the LAA. The CALMET® model domain is shown on Map 5 in Appendix A.

The CALMET® model used mesoscale meteorological data with a 12 km grid resolution created with the WRF mesoscale prognostic model and incorporated surface meteorological observations from Lynn Lake Airport. The CALMET® model was used to adjust the WRF initial guess field for the kinematic effects of terrain, slope flows, and terrain blocking effects using the finer scaled terrain data to produce a wind field with a horizontal resolution of 500 m. Details on the CALMET® model implementation are provided in Appendix D. All recommended default CALMET® options in the Alberta Air Quality Model Guideline (AEP 2013) were applied.

The CALMET® five-year meteorological data (2012-2016) is viewed as being representative of the wide range of weather conditions that could occur in the region. The wind rose derived for the Project from the CALMET® model indicates dominant winds from northwest which are in good agreement with the measured winds at the Lynn Lake Airport.

7.3 CALPUFF DISPERSION MODEL

The CALPUFF® atmospheric dispersion model (Scire et al. 2000b; 2011) was used to simulate the transport, dispersion and deposition of emissions during operation. As discussed in Section 4.0, construction and decommissioning/closure emissions were not modelled as they are less than the worst-case (peak production) year of operation and therefore, the effects on air quality will be less than operation.

The CALPUFF® model is a multi-layer, multi-species, non-steady state puff dispersion model that can simulate the effects of time and space-varying meteorological conditions on substance transport, transformation, and removal. CALPUFF® contains algorithms for near-source effects such as building downwash, transitional plume rise, partial plume penetration, as well as long-range effects such as chemical transformation, and pollutant removal (dry deposition and wet scavenging).

The CALPUFF® model domain coincides with the LAA (50 km by 28 km) and includes the Town of Lynn Lake and the Black Sturgeon Reserve (see Map 5, Appendix A). The extent of the CALPUFF® domain is sufficient to capture the overall predicted maximum concentrations of substances of interest for the worst-case operation emission scenario. Details on the CALPUFF® model implementation are provided in Appendix E. All recommended default CALPUFF® options in the Alberta Air Quality Model Guideline (AEP 2013) were applied.

7.3.1 Model Sources

Emission sources were modelled in CALPUFF® as one of the following types depending on the nature of the source and the emission release to the atmosphere. Different input parameters are used to represent the different source types:

- **Point source**: an industrial stack; parameters required for each stack include stack height, stack diameter, stack gas exit temperature and stack gas exit velocity.
- **Area source**: emission distributed over an area; parameters required for each area source include release height and initial vertical dimension (σ_z) which accounts for the initial vertical dispersion of the plume.
- **Volume source**: a single point of emission with initial vertical and horizontal dispersion; parameters required for each volume source include release height, and initial vertical (σ_z) and horizontal dimension (σ_y) which account for the initial vertical and horizontal dispersion of the plume.
- **Line source**: emission distributed along a line, such as a road; although CALPUFF® does not have a non-buoyant line source type, the line sources for this assessment were represented in CALPUFF® by multiple volume sources.

Since CALPUFF® does not have an algorithm to model open pit sources, the open pits were modelled as surface area sources with reduced PM emissions to account for the fraction of PM emissions retained in the open pit due to its depth, known as “pit retention”. Pit retention is the term used to describe the tendency for PM emissions released inside an open mine pit to remain inside the pit. The fraction of PM emissions that is retained in the open pit depends on the depth of the pit and the particle size (Winges 1986). A 50% pit retention for TSP emissions and 5% pit retention for PM_{10} emissions was applied based on recommendation in the Australian Emission Manual for Mining (Australian Government 2012). The fraction of $PM_{2.5}$ emissions retained in the open pits was estimated based on the original Winges equation (Winges 1981) assuming a pit depth of 150 m for Gordon site (Year 2) and 245 m for MacLellan site (Year 7). The calculated pit retention fraction of $PM_{2.5}$ emissions is 1% for the open pit at Gordon site and 2% for the open pit at MacLellan site. Details on the pit retention fractions used for PM emissions from the open pits at Gordon and MacLellan sites are provided in Appendix C. All emission sources in the open pit are modelled as a surface area source representing the open pit, including drilling and blasting emissions, diesel exhaust emissions from mining off-road equipment operating in the pit and fugitive dust emissions from mining off-road equipment movement, bulldozing, grading and truck loading.

A number of emission sources are modelled as multiple volume sources in the air dispersion model and are allocated at mine areas such as the MRSA, overburden stockpiles, ore stockpiles, and the ROM stockpile and primary crusher at MacLellan site. These include:

- Diesel exhaust emissions from mining off-road equipment.
- Mechanically generated dust emissions by mining off-road equipment movement.

- Fugitive dust emissions from bulldozing and grading.
- Fugitive dust emissions from truck loading and unloading.

Diesel exhaust emissions and mechanically generated dust emissions from supporting equipment are allocated to general areas at the truck stop and warehouse facilities at Gordon site and at the ore milling and processing plant at MacLellan site. The general areas are modelled as area sources in the air dispersion model.

Wind erosion emissions are generated when material is lifted from the surface of the stockpiles or exposed areas during a wind gust. The stockpiles and the TMF dry banks are treated as area sources for wind erosion emissions. These area sources are modelled with varying hourly emission rates depending on the wind speed.

Diesel exhaust emissions and mechanically generated dust emissions from haul trucks travelling along the haul roads are allocated along the length of the haul roads. Similarly, traffic emissions from on-highway trucks and on-road vehicles travelling on the access roads and PR 391 are allocated to the length of the access roads and PR 391. Traffic emissions, including diesel exhaust and mechanically generated dust emissions, are modelled as line sources in the air dispersion model.

The primary crusher dust collector stack, the secondary crusher wet scrubber stack and the gold room dust collector stacks at MacLellan site, and the diesel generator at Gordon site are modelled as point sources with their design stack parameters in the air dispersion model.

At the MacLellan site, fugitive HCN emissions result from volatilization of sodium cyanide used in the ore milling and processing plant leach and adsorption tanks, and from residual cyanide (after cyanide detoxification) in the TMF pond. The fugitive HCN emissions from the ore milling and processing plant were modelled as a volume source placed at leach tank. Fugitive HCN emissions from the TMF pond were modelled as an area source at the TMF pond surface.

Gordon Site

In total, 16 sources were created in CALPUFF® to model Gordon site operation emissions. Detailed source parameters for the modelled emissions sources are provided in Appendix E. The modelled emission sources for Gordon site operation are shown on Map 6 in Appendix A. These sources include:

- Three collocated open pit sources representing blasting (PIT_BL_G), haul roads (PIT_HR_G) and mining off-road equipment diesel exhaust and fugitive dust emissions (PIT_LB_G) in the open pit, respectively.
- Three groups of volume sources representing diesel exhaust emissions from mining off-road equipment, mechanically generated dust emissions by mining off-road equipment movement and fugitive dust emissions from bulldozing, grading and truck loading and unloading at the MRSA (MH_WR_G), the overburden stockpile (MH_OVB_G) and the ore stockpile (MH_LG_G). The volume

source groups include four volume sources representing the most probable locations of equipment and mining activities.

- One area source (GA_G) representing diesel exhaust and fugitive dust emissions from supporting equipment at the truck stop and warehouse general area of Gordon site.
- Three area sources representing wind erosion emissions from the MRSA, the overburden and ore stockpiles.
- One point source representing the diesel generator stack.
- Three line sources (consisting of multiple volume sources) representing diesel exhaust emissions and mechanically generated dust emissions from haul trucks along the haul roads from the open pit to the MRSA (HR_PWR_G), from the open pit to the overburden stockpile (HR_POB_G) and from the open pit to the ore stockpile (HR_PLG_G).
- One line source (consisting of multiple volume sources) representing diesel exhaust emissions and mechanically generated dust emissions from on-highway trucks and on-road vehicles along the access road to the Gordon site (AR_G).
- One line source (consisting of multiple volume sources) representing diesel exhaust emissions and mechanically generated dust emissions from haul trucks transporting ore from the Gordon site to the MacLellan site ore milling and processing plant and from other on-highway trucks carrying fuel, explosives and consumables for the ore milling and processing plant and on-road vehicles travelling on PR 391.

MacLellan Site

In total, 28 sources were created to model MacLellan site operation emissions. Detailed source parameters for the modelled emissions sources are provided in Appendix E. The modelled emission sources for MacLellan site operation are shown on Map 7 in Appendix A. These sources include:

- Three collocated open pit sources representing blasting (PIT_BL_M), haul roads (PIT_HR_M) and mining off-road equipment diesel exhaust and fugitive dust emissions (PIT_LB_M) in the open pit, respectively.
- Four groups of volume sources representing diesel exhaust emissions from mining off-road equipment, mechanically generated dust emissions by mining off-road equipment movement and fugitive dust emissions from bulldozing, grading and truck loading and unloading at the MRSA (MH_WR_M), the overburden stockpile (MH_OVB_M), the ore stockpile and ROM stockpile (MH_LG_M) and the primary crusher (MH_PC_M). The volume source groups include two to four volume sources representing the most probable locations of equipment and mining activities.

- One volume source (VPLANT) representing fugitive HCN emissions from the leach and adsorption tanks at the ore milling and processing plant.
- One area source (GA_M) representing diesel exhaust and fugitive dust emissions from supporting equipment at the general area of the MacLellan site.
- Seven area sources representing wind erosion emissions from the MRSA, the overburden, topsoil, ore and ROM stockpiles and from the TMF dry banks.
- Four point sources representing the primary crusher dust collector stack, the secondary crusher wet scrubber stack and the gold room dust collector stacks.
- Five line sources (consisting of multiple volume sources) representing diesel exhaust emissions and mechanically generated dust emissions from haul trucks along the haul roads from the open pit to the primary crusher (HR_PM_M), from the open pit to the MRSA (HR_PWR_M), from the open pit to the overburden stockpile (HR_POB_M), from the open pit to the ore stockpile (HR_PLG_M) and from the open pit to the ROM stockpile.
- Three line sources (consisting of multiple volume sources) representing diesel exhaust emissions and mechanically generated dust emissions from on-highway trucks and on-road vehicles along the access roads to the mill feed and processing plant (ARO_M), to the explosives facilities (AR_EM_M) and to the permanent work camp (AR_WC_M).

7.3.2 Receptors and Terrain

Ambient ground-level concentration and deposition patterns were predicted at receptor grid locations within the CALPUFF® model domain and outside the Project Boundary. A nested receptor grid with increased receptor density with proximity to the Project Boundary was created in the model domain following the spacing requirements in the Draft Guidelines for Air Dispersion Modelling in Manitoba (Manitoba Conservation, 2006) and the Air Dispersion Modelling Guideline for Ontario (MOECC 2016) as follows:

- 20 m spacing along the Project Boundary at the Gordon and MacLellan sites.
- 100 m spacing along the Project Boundary around the access roads to the Gordon and MacLellan sites.
- 250 m spacing along the Project Boundary around PR 391.
- 50 m spacing within 500 m of the Project Boundary.
- 100 m spacing within 1.3 km of the Project Boundary.
- 200 m spacing within 2.1 km of the Project Boundary.
- 500 m spacing within 6.9 km of the Project Boundary.

- 1,000 m spacing beyond 6.9 km of the Project Boundary.

The receptor grid consists of 14,997 receptor points. The receptor grid is shown on Map 8 in Appendix A.

In addition, concentrations and depositions were predicted at 203 human receptors and Potential Indigenous Receptor sites and at the Permanent Worker Camp to provide input to the human health assessment. Map 3 in Appendix A shows the locations of human receptors and Potential Indigenous Receptor sites in the LAA. A list of the 203 human receptors and Potential Indigenous Receptor sites and the permanent work camp location is provided in Appendix E.

Terrain elevations were estimated for the receptor locations based on an integrated Light Detection and Ranging (LiDAR) and Shuttle Radar Topography Mission (SRTM) digital elevation data. The LiDAR data is a high-resolution data set with an approximate spatial resolution of 5 m that was custom developed for the Gordon and MacLellan sites from aerial surveys. However, the LiDAR data covers only the Gordon and MacLellan sites. To use the high-resolution LiDAR data for the air quality assessment, the LiDAR data was integrated with US Geological Survey (USGS) SRTM data with a spatial resolution of approximately 30 m (USGS 2014) to cover the full extent of the LAA. The terrain elevations in the LAA based on the integrated LiDAR and SRTM data are shown on Map 9 in Appendix A.

7.3.3 Building Downwash Effects

Buildings or other solid structures may affect air flow near a source and cause building downwash effects (e.g., eddies on the downwind side), which have the potential to reduce plume rise and affect atmospheric dispersion. Building downwash effects may occur if the height of the stack is less than 2.5 times the height of an adjacent building. Adjacent buildings may also affect the stack if the stack is located in the building's region of influence defined as a distance of 5 times the lesser of the width or height of the crosswind face of the building.

Building downwash effects were considered for all stack emissions using the US EPA Building Profile Input Program (BPIP; US EPA 1995b). BPIP provides parameters that are used by the Plume Rise Model Enhancement (PRIME) downwash algorithms in CALPUFF®. Map 6 in Appendix A shows the locations of the buildings and stacks at the Gordon site. Map 7 in Appendix A shows the locations of the buildings and stacks at the MacLellan site. All buildings and structures, including tanks, that have potential to cause building downwash effects were included in the BPIP PRIME model. The dimensions of the buildings and structures considered in the dispersion model for Gordon and MacLellan sites are listed in Table 7-1.

Table 7-1 Buildings and Structures included in CALPUFF®

Building Description	Building ID	Length (m)	Width (m)	Height (m)
Gordon Site				
Generator	DGEN	15	12	3.5
Wash Bay/Truckstop Warehouse	WBAY	80	24	6
MacLellan Site				
Administration	ADMIN	25.2	65.1	3
Warehouse workshop	WAREH	12.5	25	6
Primary Crushing	PC	36	23	19.6
Secondary Crushing	SC	15	15	23
Grinding	GRIND	32.1	39.5	26
CIP	CIP	30	43	22
Reagents	REAGENT	15	42	15
Gold room	GR	12	18.6	8
Assay lab	ASSAY	10	14.7	3
Oxygen Plant	OP	24	10	4
Crushed Ore Stockpile Building	OS	100	100	30
Truck Shop	TSM	30.5	63.4	19.3
Truck Wash	TRWM	19.2	29.9	15.5
Pre-leach Thickener	PLT	32	32	9.0
Pre-aeration Tank	PAT	14.9	14.9	16.4
Leach Tank 1	LT1	14.9	14.9	16.4
Leach Tank 2	LT2	14.9	14.9	16.4
Leach Tank 3	LT3	14.9	14.9	16.4
Leach Tank 4	LT4	14.9	14.9	16.4
Process Water Tank	PRT	10	10	7.8
Fresh Water Tank	FRT	10	10	13
Cyanide Detox Tank	CDT	8.8	8.8	9.8

7.3.4 NO to NO_2 Conversion

NO_X is composed of NO and NO_2. Most of the NO_X emissions are in the form of NO which is converted in the atmosphere to NO_2 during reactions with ambient ozone (O_3). Due to the inert nature of NO, only NO_2 concentrations are regulated by the AAQC.

Atmospheric chemistry, including atmospheric transformation of NO to NO_2, was not simulated in CALPUFF®. NO_X was modelled as a trace specie without any chemical transformations. The Ozone

Limiting Method (OLM) was applied to the NO_X predictions to estimate the fraction of NO_2 that is contained in the NO_X plume.

The OLM method accounts for the oxidation of NO to NO_2 due to photochemical reactions in the atmosphere in the presence of ambient O_3. According to the OLM method, the conversion of NO to NO_2 is limited by the ambient concentration of O_3 in the atmosphere. It is assumed that 10% (by volume) of the NO_X emission release from the source is in the form of NO_2 and the remaining 90% is converted to NO_2 as follows:

- If 90% of NO_X concentration is less than the ambient O_3 concentration, then

  $[NO_2]= [NO_X]$(complete conversion).

- If 90% of NO_X concentration is greater than the ambient O_3 concentration, then

  $[NO_2]= 10\% [NO_X]+ [O_3]$ (limited conversion).

In the application of the OLM, the above relationships assume that all concentrations are expressed in parts per million (ppm).

As no on-site O_3 data is available, O_3 measurements from the Fort Smith monitoring station in Northwest Territories were used in the OLM conversion calculations. The Fort Smith station is considered the most representative for the LAA as the station is in a similarly remote area with low population density and with similar meteorological and topographical conditions. Hourly O_3 data from Fort Smith station was downloaded for the three-year period 2016 to 2018. An hourly time-series of O_3 values was compiled using the maximum measured O_3 concentration for each hour from the three-year period. Therefore, the hourly O_3 time-series used in the OLM conversion are conservative. The maximum O_3 concentration measured for the three-year period 2016 to 2018 was 71 ppb.

7.3.5 Particulate Matter Deposition

Dry deposition of PM is the process of settling of particles on the ground due to gravity and micro meteorological and atmospheric processes. Wet deposition is the depletion of particles from the atmosphere by rain or snow. Dry and wet deposition of total PM are modelled in CALPUFF®. PM deposition is also referred to as dustfall.

Different physical processes govern the settling of PM of different sizes. For larger PM (greater than 20 µm), dry deposition is caused mainly by gravitational settling, deposition of smaller PM is caused by micro meteorological and atmospheric processes. Wet deposition is proportional to the precipitation rate and a scavenging coefficient which depends on the particle size.

For deposition modelling, total PM is represented with a particle size distribution consisting of the following particle size categories:

- Particles with aerodynamic diameter smaller than 2.5 µm represented with a geometric mean aerodynamic diameter of 1.6 µm.

- Particles with aerodynamic diameter between 2.5 and 10 µm represented with a geometric mean aerodynamic diameter of 6.9 µm.
- Particles with aerodynamic diameter between 10 and 30 µm represented with a geometric mean aerodynamic diameter of 21.5 µm.

Emission rates for each particle size category are derived from particle size-specific emission factors representative of the various construction and mining activities.

Wet deposition fluxes due to precipitation scavenging are calculated in CALPUFF® using an empirical scavenging coefficient approach. The scavenging coefficients are specified as a function of the particle size and precipitation type (i.e., frozen vs. liquid precipitation). Total dustfall is estimated as the sum of modelled dry and wet deposition for each particle size category.

7.3.6 Atmospheric Chemistry and Formation of Secondary PM2.5

Atmospheric chemistry is not simulated in CALPUFF®. Thus, secondary formation of fine particulate matter ($PM_{2.5}$) from nitrates and sulphates is not modelled. The formation of secondary PM is not considered substantial compared to the amount of fugitive dust generated from the various construction and mining activities.

8.0 DISPERSION MODEL RESULTS

The maximum predicted ambient concentrations and dustfall for the substances of interest are predicted for the worst-case year of operation at Gordon site and ore haul on PR 391 (Year 2) and the worst-case year of operation at MacLellan site (Year 7). The model predicted 1-hour and 8-hour average concentrations are based on the maximum hourly emission rates. The model predicted 24-hour, monthly and average concentrations are based on the daily average emission rates that consider the actual operating hours per day for each mining activity.

Baseline concentrations are added to the model predicted maximum concentrations to account for other existing emission sources (natural and anthropogenic) that are not directly included in the model simulation. The model predicted maximum concentrations with the baseline contribution are compared to the Manitoba AAQC and the CAAQS. The CAAQS are reference values for regional air quality management and are applicable to measured ambient concentrations at human receptor locations away from the industrial facility boundaries. The maximum predicted concentrations in the LAA are compared to the CAAQS in this context and do not imply compliance with the AAQC at the Project Boundary. The maximum predicted concentrations are based on areas along and outside the Project Boundary (i.e., locations where public access is not restricted). The predicted maximum concentrations and dustfall are discussed separately for Gordon site and MacLellan site in the following sections. The corresponding concentration contour maps are presented in Appendix G. The colored contours represent concentrations greater than 10% of the respective AAQC or in case of the background concentration greater than 10% of the AAQC (e.g., annual TSP, $PM_{2.5}$ and dustfall) – greater than the background value. The concentration contour maps presented in Appendix G are limited to the substances and averaging periods for which maximum predicted concentrations are greater than 10% of the AAQC.

Additionally, a source contribution analysis was completed to determine the relative contribution of each emission source or source group to the maximum predicted concentrations at a specific location. The source contribution analysis identifies the most contributing emission sources to predicted high ambient concentrations and indicates the best target(s) for application of the most effective mitigation options.

The model predicted maximum ambient VOC, PAH and metal concentrations, and PAH and metal depositions are evaluated in the human health assessment.

8.1 GORDON SITE OPERATION

The model predicted maximum ground-level concentrations and dustfall from Gordon site operation are summarized in Table 8-1. These maximum predicted concentrations in Table 8-1 are presented for the following areas:

- An overall maximum in the LAA.
- Maximum predicted concentrations at human receptors.
- Maximum predicted concentrations within Black Sturgeon Reserve. Concentrations are predicted at 30 grid receptors spaced at 500 m to 1,000 m covering the Black Sturgeon Reserve and 30 discrete receptors in Black Sturgeon Reserve (i.e., 14 residences, 1 infrastructure receptor, 2 potential residences and 13 Potential Indigenous Receptors).
- Maximum predicted concentrations along PR 391. Concentrations are predicted at discrete receptors located along PR 391 with a buffer of 300 m from both sides of the road and spaced at 250 m.

The associated concentration and dustfall contours in the LAA, including human receptors, Black Sturgeon Reserve and PR 391, are presented in Map G-1 to Map G-25 in Appendix G.

The maximum 1-hour average NO_2, CO and SO_2 concentrations and 24-hour average TSP and PM_{10} concentrations are greater than the respective AAQC and the CAAQS. For the other gaseous and PM CACs, dustfall and metals, the maximum predicted values are less than the applicable AAQC. The highest model predicted concentrations from Gordon site operation for all substances of interest occur along the Project Boundary and reduce with increased distance from the boundary. Predicted HCN concentrations in Black Sturgeon Reserve and along PR 391 are associated entirely with air emissions from the ore milling and processing plant and the TMF at MacLellan site.

Maximum NO_2 Concentrations

The maximum predicted 1-hour NO_2 concentration, 459 µg/m³, is greater than the Manitoba AAQC (400 µg/m³). The maximum predicted 24-hour and annual NO_2 concentrations are 74.1 and 11.2 µg/m³, respectively and are less than the Manitoba AAQC and the annual CAAQS. The maximum predicted 1-hour average NO_2 concentration in the metric of the CAAQS (224 µg/m³) is greater than the 1-hour CAAQS

(79 µg/m³). The maximum predicted NO_2 concentrations at sensitive receptors for all averaging periods are less than the Manitoba AAQC. The maximum predicted NO_2 concentrations are greater than the 1-hour CAAQS at three sensitive receptors. The maximum predicted NO_2 concentrations in Black Sturgeon Reserve for all averaging periods are less than the applicable AAQC and CAAQS. The maximum predicted NO_2 concentrations along PR 391 for all averaging periods are less than the Manitoba AAQC. The maximum predicted NO_2 concentrations are greater than the 1-hour CAAQS along a segment of PR 391 with an approximate length of 5 km near MacLellan site (Map G-2). Along PR 391, values greater than the 1-hour CAAQS are predicted for less than 15 days in a year.

The maximum predicted 1-hour, 24-hour and annual NO_2 concentrations occur on the northeast Project Boundary near the open pit (Maps G-1, G-4 and G-5). The predicted NO_2 concentrations greater than the 1-hour Manitoba AAQC (400 µg/m³) occur for two hours per year and are limited to the northeast Project Boundary near the open pit. There are no sensitive receptors on or near the boundary at this location.

The model predicted NO_2 concentrations greater than the 1-hour CAAQS (79 µg/m³) extend approximately 2.3 km from the Gordon site boundary (Map G-2 and G-3). Along the Project Boundary, values greater than the 1-hour CAAQS are predicted for 99 days in a year, reducing to one day per year with increasing distance. There are three sensitive receptors (trapping areas) within this area.

Maximum CO Concentrations

The maximum predicted 1-hour CO concentration, 16,096 µg/m³, is greater than the Manitoba AAQC (15,000 µg/m³). The maximum predicted 8-hour CO concentration, 4,952 µg/m³, is less than the Manitoba AAQC (6,000 µg/m³). The maximum predicted CO concentrations at sensitive receptors for all averaging periods are less than the AAQC. The maximum predicted CO concentrations in Black Sturgeon Reserve and along PR 391 for all averaging periods are less than the AAQC.

The maximum predicted 1-hour and 8-hour CO concentrations occur on the northeast Project Boundary near the open pit (Maps G-6 and G-7). The predicted CO concentrations greater than the 1-hour Manitoba AAQC (15,000 µg/m³) occur for one hour per year and are limited to the northeast Project Boundary near the open pit. There are no sensitive receptors on or near the boundary at this location.

Maximum SO_2 Concentrations

The maximum predicted 1-hour SO_2 concentration, 460 µg/m³, is greater than the Manitoba AAQC (450 µg/m³). The maximum predicted 24-hour and annual SO_2 concentrations are 48.7 and 2.45 µg/m³, respectively and are less than the Manitoba AAQC and the annual CAAQS. The maximum predicted 1-hour average SO_2 concentration in the metric of the CAAQS (342 µg/m³) is greater than the 1-hour CAAQS (170 µg/m³) (Map G-9). The maximum predicted SO_2 concentrations at sensitive receptors for all averaging periods are less than the AAQC. The maximum predicted SO_2 concentrations in Black Sturgeon Reserve and along PR 391 for all averaging periods are less than the applicable AAQC and CAAQS.

The maximum predicted 1-hour, 24-hour and annual SO_2 concentrations occur on the northeast Project Boundary near the open pit (Maps G-8, G-11 and G-12). Predicted SO_2 concentrations greater than the

1-hour Manitoba AAQC (450 µg/m³) occur for one hour per year and are limited to the northeast Project Boundary near the open pit. There are no sensitive receptors on or near the boundary at this location.

The model predicted SO_2 concentrations greater than the 1-hour CAAQS (170 µg/m³) extend approximately 400 m from the Gordon northeast boundary (Map G-9 and G-10). Along the Project Boundary, values greater than the 1-hour CAAQS are predicted for 5 days in a year, reducing to one day per year with increasing distance. There are no sensitive receptors within this area.

Maximum HCN Concentrations

The maximum predicted 1-hour, 24-hour and annual HCN concentrations are 0.592 µg/m³, 0.196 µg/m³ and 0.014 µg/m³, respectively and are less than the Manitoba AAQC and the 24-hour Ontario AAQC. The maximum predicted HCN concentrations at sensitive receptors for all averaging periods are less than the ambient criteria. The maximum predicted HCN concentrations in Black Sturgeon Reserve and along PR 391 for all averaging periods are less than the AAQC.

The maximum predicted 1-hour, 24-hour and annual HCN concentrations occur along PR 391 near MacLellan site (Maps G-13, G-14 and G-15).

Maximum TSP Concentrations

The maximum predicted 24-hour TSP concentration, 606 µg/m³, is greater than the Manitoba AAQC (120 µg/m³). The maximum predicted annual TSP concentration,14.8 µg/m³, is less than the Manitoba AAQC. The maximum predicted TSP concentrations are greater than the Manitoba 24-hour AAQC at one sensitive receptor (trapping area). The maximum predicted TSP concentrations in Black Sturgeon Reserve for all averaging periods are less than the AAQC. The maximum predicted TSP concentrations are greater than the Manitoba 24-hour AAQC along a segment of PR 391 with an approximate length of 5 km near MacLellan site (Map G-16). Along PR 391, values greater than the 24-hour AAQC are predicted for less than 15 days in a year (Map G-17).

The maximum predicted 24-hour and annual TSP concentrations occur on the north and northeast Project Boundary, respectively, near the open pit (Maps G-16 and G-18). The model predicted TSP concentrations greater than the 24-hour Manitoba AAQC (120 µg/m³) extend approximately 2.2 km from the Gordon site boundary (Map G-17). Along the Project Boundary, values greater than the 24-hour AAQC are predicted for 73 days in a year, reducing to one day per year with increasing distance. There is one sensitive receptor (trapping area) within this area.

Maximum PM_{10} Concentrations

The maximum predicted 24-hour PM_{10} concentration, 361 µg/m³, is greater than the Manitoba AAQC (50 µg/m³). The maximum predicted PM_{10} concentrations are greater than the Manitoba 24-hour AAQC at three sensitive receptors (trapping areas). The maximum predicted 24-hour PM_{10} concentrations in Black Sturgeon Reserve are less than the AAQC. The maximum predicted PM_{10} concentrations are greater than the Manitoba 24-hour AAQC along a segment of PR 391 with an approximate length of 6 km near MacLellan site (Map G-19). Along PR 391, values greater than the 24-hour AAQC are predicted for less than 15 days in a year (G-20).

The maximum predicted 24-hour PM_{10} concentration occurs on the north Project Boundary near the open pit (Maps G-19). The model predicted PM_{10} concentrations greater than the 24-hour Manitoba AAQC (50 µg/m³) extend approximately 3.3 km from the Gordon site boundary (Map G-20). Along the Project Boundary, values greater than the 24-hour AAQC are predicted for 110 days in a year, reducing to one day per year with increasing distance. There are three sensitive receptors (trapping areas) within this area.

Maximum $PM_{2.5}$ Concentrations

The maximum predicted 24-hour and annual $PM_{2.5}$ concentrations are 23.5 µg/m³ and 6.87 µg/m³, respectively, and are less than the CAAQS. The maximum predicted $PM_{2.5}$ concentrations at sensitive receptors for all averaging periods are less than the AAQC. The maximum predicted $PM_{2.5}$ concentrations in Black Sturgeon Reserve and along PR 391 for all averaging periods are less than the AAQC.

The maximum predicted 24-hour and annual $PM_{2.5}$ concentrations occur on the northeast Project Boundary near the open pit (Maps G-21 and G-22).

Maximum Dustfall

The maximum predicted 30-day and annual average dustfall are 4.90 g/m²/30-day and 1.87 g/m²/30-day and are less than the Ontario AAQC. The maximum predicted 30-day and annual average dustfall at sensitive receptors are less than the dustfall criteria. The maximum predicted 30-day and annual average dustfall in Black Sturgeon Reserve and along PR 391 are less than the dustfall criteria.

The maximum predicted 30-day and annual dustfall occur on the east Project Boundary near the open pit (Maps G-23 and G-24).

Maximum Metal Concentrations

The maximum predicted metal concentrations for all averaging periods are less than the Manitoba AAQC. The maximum predicted metal concentrations at sensitive receptors for all averaging periods are also less than the Manitoba AAQC. The maximum predicted metal concentrations in Black Sturgeon Reserve and along PR 391 for all averaging periods are less than the AAQC.

The maximum predicted 24-hour and 30-day metal concentrations occur along PR 391 near the MacLellan site. The concentration contour map for arsenic (Map G-25) is included in Appendix G because maximum predicted concentrations for arsenic are greater than 10% of the AAQC. The maximum predicted concentrations for the other metals are less than 10% of the AAQC.

NOTES:

[a] Manitoba Ambient Air Quality Criteria (MSD 2005) unless otherwise noted

[b] The maximum 1-hour concentration after eliminating 8 highest meteorological hours in each year

[c] The maximum 24-hour concentration after eliminating the 1st highest meteorological day in each year

[d] CAAQS (CCME 2017)

[e] The 1-hour CAAQS for NO_2 is referenced to the three-year average of the annual 98th percentile of the NO_2 daily maximum 1-hour average concentrations (effective 2025) (CCME 2017).

[f] The annual CAAQS for NO_2 is referenced to the arithmetic average over a single calendar year of all 1-hour average NO_2 concentrations (effective 2025) (CCME 2017).

[g] The 1-hour CAAQS for SO_2 is referenced to the three-year average of the annual 99th percentile of the SO_2 daily maximum 1-hour average concentrations (effective 2025) (CCME 2017).

[h] The annual CAAQS for SO_2 is referenced to the arithmetic average over a single calendar year of all 1-hour average SO_2 concentrations (effective 2025) (CCME 2017).

[i] Ontario AAQC (MOECC 2012)

[j] Annual geometric mean

[k] The CAAQS for 24-hour $PM_{2.5}$ is referenced to the annual 98th percentile of daily 24-hour average concentrations, averaged over three years (effective 2020) (CCME 2017).

Table 8-1 Predicted Maximum Ground-Level Concentrations from Gordon Site Operation

Substance	Averaging Period	Existing/ Baseline Conditions (µg/m³)	Maximum Ground-level Concentration (µg/m³) (includes Baseline Conditions)						Ambient Air Quality Criteria [a] (µg/m³)
			Max. Value in LAA	Max. Value at Human Receptors	Max. Value in Black Sturgeon Reserve	Max. Value along PR 391	Max. No. of Exceedances per Year	% Max. Value of AAQC	

[l] The CAAQS for annual $PM_{2.5}$ is referenced to the three-year mean of annual average concentrations (effective 2020) (CCME, 2017).
Predicted maximum 1-hour and 8-hour average concentrations are based on maximum hourly emission rates.
Predicted maximum 24-hour, 30-day and annual average concentrations are based on daily average emission rates.
Values in **BOLD** exceed the ambient air quality criteria

8.1.2 Source Contribution Analysis

A source contribution analysis for the Gordon site was completed for the maximum predicted 24-hour average concentrations at the northeast Project Boundary near the open pit (413133 m E, 6307554 m N, UTM Zone 14) as this is the general location of the maximum predicted concentrations for most of the substances of interest. Only substances with maximum predicted concentrations greater than 10% of the AAQC were considered in the analysis. For NO_2, the NO_X concentrations were used to discount any artificial effects of the OLM conversion of NO_X to NO_2.

The emission sources were grouped into categories by common emission pathways, such as blasting and explosives detonation, mining equipment and material handling, wind erosion, diesel generator, haul roads, access roads and PR 391. Table 8-2 presents the seven source groups used in the source contribution analysis at Gordon site.

To understand the relative importance of emission sources to high predicted concentrations and to evaluate the most effective mitigation options, the maximum predicted "worst-day" (24-hour) concentrations for each source group was used without consideration of temporal overlap (the "worst-day" for one substance may not overlap with the "worst-day" for another substance).

Table 8-2 Source Groups for the Source Contribution Analysis at the Gordon Site

Source Group Description	Source ID
Blasting and Explosives Detonation [a]	BL
Mining Equipment and Material Handling [b]	ME
Wind Erosion [c]	WE
Diesel Generator [d]	DG
Haul Roads [b]	HR
Access Road [b]	AR
PR 391 [b]	PR 391

NOTES:
[a] Emission sources include detonation of ammonium nitrate fuel oil emulsion explosives and fugitive dust emissions
[b] Emission sources includes diesel exhaust emissions and fugitive dust emissions
[c] Emission sources include fugitive dust emissions
[d] Emission source includes diesel exhaust emissions

Figure 8-1 illustrates the relative contributions of the seven source groups to the maximum predicted 24-hour concentrations at the northeast Project Boundary at the Gordon site for each substance of interest. The source contribution analysis is presented for each substance of interest below.

NO_2 (NO_X)

The explosives detonation in the open pit is the largest contributor to the maximum predicted 24-hour NO_X concentrations at the northeast Project Boundary (BL: 79%) followed by haul trucks (HR: 14%) and other mining equipment (ME: 7%). Smaller contributors include the diesel generator (DG: 0.4%), the access road vehicles (AR: 0.1%) and the PR 391 vehicles (PR 391: 0.01%) with a combined contribution less than 1%. Wind erosion (WE) is not a source of NO_X emissions and therefore, has no contribution to predicted NO_X concentrations.

CO

The explosives detonation in the open pit is the largest contributor to the maximum predicted 24-hour CO concentrations at the northeast Project Boundary (BL: 94%) followed by haul trucks (HR: 4%) and other mining equipment (ME: 2%). Smaller contributors include the diesel generator (DG: 0.01%), the access road vehicles (AR: 0.01%) and the PR 391 vehicles (PR 391: 0.001%) with a combined contribution less than 1%. Wind erosion (WE) is not a source of CO emissions and therefore, has no contribution to predicted CO concentrations.

SO_2

The explosives detonation in the open pit is the sole largest contributor to the maximum predicted 24-hour SO_2 concentrations at the northeast Project Boundary (BL: 100%). The haul trucks (HR: 0.3%), the mining equipment (ME: 0.2%), the diesel generator (DG: 0.005%), the access road vehicles (AR: 0.002%) and the PR 391 vehicles (PR 391: 0.0003%) have a combined contribution of less than 1%. Wind erosion (WE) is not a source of SO_2 emissions and therefore, has no contribution to predicted SO_2 concentrations.

TSP

The haul roads are the largest contributor to the maximum predicted 24-hour TSP concentrations at the northeast Project Boundary (HR: 47%) followed by fugitive dust from mining equipment and material handling (ME: 42%), blasting (BL: 8%) and the access road (AR: 3%). The remaining three source groups – the diesel generator (DG: 0.03%), PR 391 (PR 391: 0.02%) and wind erosion (WE: 0.04%) have a combined contribution of less than 1%.

PM_{10}

The haul roads are the largest contributor to the maximum predicted 24-hour PM_{10} concentrations at the northeast Project Boundary (HR: 44%) followed by fugitive dust from mining equipment and material handling (ME: 40%), blasting (BL: 12%) and the access road (AR: 4%). The remaining three source groups - the diesel generator (DG: 0.05%), PR 391 (PR 391: 0.03%) and wind erosion (WE: 0.03%) have a combined contribution of less than 1%.

$PM_{2.5}$

The fugitive dust from mining equipment and material handling is the largest contributor to the maximum predicted 24-hour $PM_{2.5}$ concentrations at the northeast Project Boundary (ME: 48%) followed by haul roads (HR: 41%), blasting (BL: 7%) and the access road (AR: 4%). The remaining three source groups - the diesel generator (DG: 0.1%), PR 391 (PR 391: 0.1%) and wind erosion (WE: 0.1%) have a combined contribution of less than 1%.

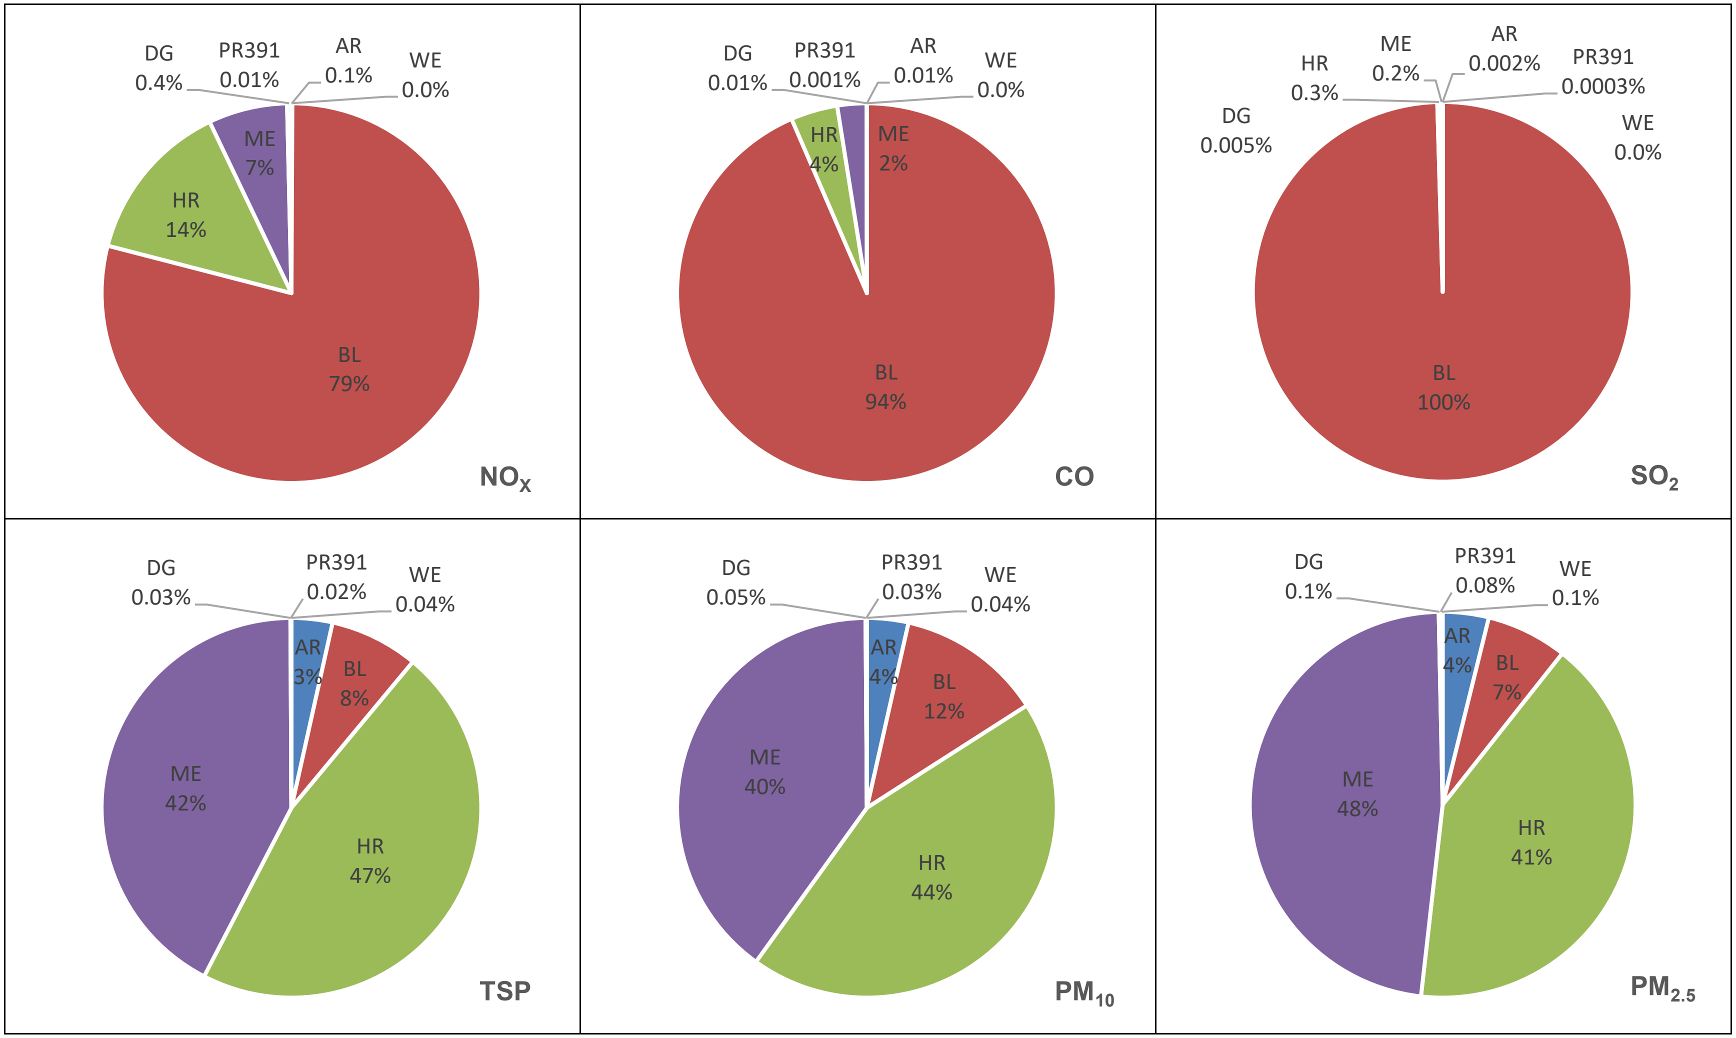

Figure 8-1 Source Contributions to Maximum Predicted 24-hour Concentrations at the Northeast Project Boundary at Gordon Site

8.2 MACLELLAN SITE OPERATION

The predicted maximum ground-level concentrations and dustfall from MacLellan site operation are summarized in Table 8-3. These maximum predicted concentrations in Table 8-3 are presented for the following areas:

- An overall maximum in the LAA.
- Maximum predicted concentrations at human receptors.

The associated concentration and dustfall contours in the LAA, including human receptors, are presented in Map G-1 to Map G-25 in Appendix G.

The maximum 1-hour average NO_2 concentrations and 24-hour average TSP and PM_{10} concentrations are greater than the respective AAQC and the CAAQS. For the other gaseous and particulate CACs, dustfall and metals, the maximum predicted values are less than the applicable AAQC. The highest predicted concentrations from MacLellan site operation for all substances of interest occur along the Project Boundary and reduce with increased distance from the boundary.

Maximum NO_2 Concentrations

The maximum predicted 1-hour NO_2 concentration, 404 µg/m³, is greater than the Manitoba AAQC (400 µg/m³). The maximum predicted 24-hour and annual NO_2 concentrations are 84.5 and 9.03 µg/m³, respectively, and are less than the Manitoba AAQC and the annual CAAQS. The maximum predicted 1-hour average NO_2 concentration in the metric of the CAAQS (146 µg/m³) is greater than the 1-hour CAAQS (79 µg/m³). The maximum predicted NO_2 concentrations at sensitive receptors for all averaging periods are less than the Manitoba AAQC. The maximum predicted NO_2 concentrations are greater than the 1-hour CAAQS at four sensitive receptors.

The maximum predicted 1-hour, 24-hour and annual NO_2 concentrations occur on the south and southwest Project Boundary near the ore milling and processing plant (Maps G-1, G-4 and G-5). The predicted NO_2 concentrations greater than the 1-hour Manitoba AAQC, 400 µg/m³, occur for one hour per year and are limited to the south Project Boundary near the ore milling and processing plant. There are no sensitive receptors on or near the boundary at this location.

The predicted NO_2 concentrations greater than the 1-hour CAAQS, 79 µg/m³, extend approximately 3.5 km from the MacLellan site boundary (Map G-2 and G-3). Along the Project Boundary, values greater than the 1-hour CAAQS are predicted for 79 days in a year, reducing to one day per year with increasing distance. There are four sensitive receptors (a youth camp, two trapping areas and a waste disposal site) within this area. The status of the youth camp is unknown because there were reports of a fire and it is unclear if the camp will be operational in the future.

Maximum CO Concentrations

The maximum predicted 1-hour and 8-hour CO concentrations are 13,328 μg/m³ and 4,144 μg/m³, respectively and are less than the Manitoba AAQC. The maximum predicted CO concentrations at sensitive receptors for all averaging periods are less than the AQC.

The maximum predicted 1-hour and 8-hour CO concentrations occur on the south and southwest Project Boundary, respectively, near the ore milling and processing plant (Maps G-6 and G-7).

Maximum SO_2 Concentrations

The maximum predicted 1-hour, 24-hour and annual SO_2 concentrations are 370 μg/m³, 39.0 μg/m³ and 1.95 μg/m³, respectively and are less than the Manitoba AAQC and the annual CAAQS. The maximum predicted 1-hour average SO_2 concentration in the metric of the CAAQS (147 μg/m³) is less than the 1-hour CAAQS (170 μg/m³) (Map G-9). The maximum predicted SO_2 concentrations at sensitive receptors for all averaging periods are less than the AAQC.

The maximum predicted 1-hour, 24-hour and annual SO_2 concentrations occur on the southwest Project Boundary near the ore milling and processing plant (Maps G-8, G-11 and G-12).

Maximum HCN Concentrations

The maximum predicted 1-hour, 24-hour and annual HCN concentrations are 14.4 μg/m³, 6.50 μg/m³ and 0.55 μg/m³, respectively and are less than the Manitoba AAQC and the 24-hour Ontario AAQC. The maximum predicted HCN concentrations at sensitive receptors for all averaging periods are less than the ambient criteria.

The maximum predicted 1-hour, 24-hour and annual HCN concentrations occur on the northwest Project Boundary near the TMF (Maps G-13, G-14 and G-15).

Maximum TSP Concentrations

The maximum predicted 24-hour TSP concentration, 513 μg/m³, is greater than the Manitoba AAQC (120 μg/m³). The maximum predicted annual TSP concentration, 14.2 μg/m³, is less than the Manitoba AAQC. The maximum predicted TSP concentrations are greater than the Manitoba 24-hour AAQC at three sensitive receptors (two trapping areas and a waste disposal site).

The maximum predicted 24-hour and annual TSP concentrations occur on the southwest Project Boundary near the ore milling and processing plant (Maps G-16 and G-18). The predicted TSP concentrations greater than the 24-hour Manitoba AAQC, 120 μg/m³, extend approximately 2.7 km from the MacLellan site boundary (Map G-17). Along the Project Boundary, values greater than the 24-hour AAQC are predicted for 64 days in a year, reducing to one day per year with increasing distance. There are three sensitive receptors (two trapping areas and a waste disposal site) within this area.

Maximum PM_{10} Concentrations

The maximum predicted 24-hour PM_{10} concentration, 315 µg/m³, is greater than the Manitoba AAQC (50 µg/m³). The maximum predicted PM_{10} concentrations are greater than the Manitoba 24-hour AAQC at five sensitive receptors (a youth camp, three trapping areas and a waste disposal site). The status of the youth camp is unknown because there were reports of a fire and it is unclear if the camp will be operational in the future.

The maximum predicted 24-hour PM_{10} concentration occurs on the southeast Project Boundary near the ore milling and processing plant (Map G-19). The predicted PM_{10} concentrations greater than the 24-hour Manitoba AAQC (50 µg/m³) extend approximately 4.2 km from the MacLellan site boundary (Map G-20). Along the Project Boundary, values greater than the 24-hour AAQC are predicted for 89 days in a year, reducing to one day per year with increasing distance. There are five sensitive receptors (a youth camp, three trapping areas and a waste disposal site) within this area. Currently, the youth camp is inactive.

Maximum $PM_{2.5}$ Concentrations

The maximum predicted 24-hour and annual $PM_{2.5}$ concentrations are 24.1 µg/m³ and 6.23 µg/m³ and are less than the CAAQS. The maximum predicted $PM_{2.5}$ concentrations at sensitive receptors for all averaging periods are less than the AAQC.

The maximum predicted 24-hour and annual $PM_{2.5}$ concentrations occur on the southwest Project Boundary near the ore milling and processing plant (Maps G-21 and G-22).

Maximum Dustfall

The maximum predicted 30-day and annual average dustfall are 5.51 g/m²/30-day and 1.97 g/m²/30-day and are less than the Ontario AAQC. The maximum predicted 30-day and annual average dustfall at sensitive receptors are less than the dustfall criteria.

The maximum predicted 30-day and annual dustfall occur on the southeast Project Boundary near the ore milling and processing plant. (Maps G-23 and G-24).

Maximum Metal Concentrations

The maximum predicted metal concentrations for all averaging periods are less than the Manitoba AAQC. The maximum predicted metal concentrations at sensitive receptors for all averaging periods are also less than the AAQC. The maximum predicted 24-hour and 30-day metal concentrations occurs on the southwest and south Project Boundary near the ore milling and processing plant. A concentration contour map is presented only for arsenic (Map G-25) because the maximum predicted concentrations for arsenic are greater than 10% of the AAQC. The maximum predicted concentrations for the other metals are less than 10% of the AAQC.

Table 8-3 Predicted Maximum Ground-Level Concentrations from MacLellan Site Operation

Substance	Averaging Period	Existing/ Baseline Conditions (µg/m³)	Maximum Ground-level Concentration (µg/m³) (includes Baseline Conditions)				Ambient Air Quality Criteria [a] (µg/m³)

[j] Annual geometric mean

[k] The CAAQS for 24-hour $PM_{2.5}$ is referenced to the annual 98th percentile of daily 24-hour average concentrations, averaged over three years (effective 2020) (CCME 2017).

[l] The CAAQS for annual $PM_{2.5}$ is referenced to the three-year mean of annual average concentrations (effective 2020) (CCME 2017).

Predicted maximum 1-hour and 8-hour average concentrations are based on maximum hourly emission rates.

Predicted maximum 24-hour, 30-day and annual average concentrations are based on daily average emission rates.

Values in **BOLD** exceed the ambient air quality criteria

8.2.2 Source Contribution Analysis

A source contribution analysis for MacLellan site was completed for the maximum predicted 24-hour average concentrations at the permanent work camp (380916 m E, 6308622 m N, UTM Zone 14) because of its proximity to emission sources at the MacLellan site and because the permanent work camp is included in the human health assessment. Only the substances with maximum predicted concentrations greater than 10% of the AAQC were considered. For NO_2, the NO_X concentrations were used to discount any artificial effects of the OLM conversion of NO_X to NO_2.

The CAC and HCN emission sources were grouped into categories by common emission pathways, such as blasting and explosives detonation, mining equipment and material handling, wind erosion, ore milling and processing plant, TMF pond, haul roads, access roads and PR 391. Table 8-2 presents the eight source groups used in the source contribution analysis for CACs and HCN at MacLellan site.

Arsenic is the only metal with maximum predicted 24-hour concentrations greater than 10% of the AAQC at MacLellan site. The emission sources for arsenic (As) were grouped into diesel exhaust and five PM sources that contain As: mine rock, ore, overburden, road dust and tailings. Table 8-5 presents the six source groups used in the source contribution analysis for As at MacLellan site.

To understand the relative importance of emission sources to high predicted concentrations and to evaluate the most effective mitigation options, the maximum predicted "worst-day" (24-hour) concentrations for each source group were used without consideration of temporal overlap (the "worst-day" for one substance may not overlap with the "worst-day" for another substance).

Table 8-4 Source Groups for the Source Contribution Analysis of CACs and HCN at the MacLellan Site

Source Group Description	Source ID
Blasting and Explosives Detonation [a]	BL
Mining Equipment and Material Handling [b]	ME
Wind Erosion [c]	WE
Mill Feed Crushing Plant and Ore Milling and Processing Plant [d]	PP
TMF Pond [e]	TMF
Haul Roads [b]	HR
Access Roads [b]	AR

NOTES:
[a] Emission sources include explosives detonation emissions and fugitive dust emissions
[b] Emission sources includes diesel exhaust emissions and fugitive dust emissions
[c] Emission sources include fugitive dust emissions
[d] Emission sources include PM emissions from dust collectors and wet scrubbers and fugitive HCN emissions
[e] Emission sources include fugitive HCN emissions

Table 8-5 Source Groups for the Source Contribution Analysis of Arsenic at MacLellan Site

Source Group Description	Source ID
Diesel Exhaust [a]	DE
Mine Rock [b]	MR
Ore [c]	OR
Overburden [b]	OB
Road Dust [b]	RD
Tailings [b]	TMF

NOTES:
[a] Emission sources include diesel exhaust emissions
[b] Emission sources include fugitive dust emissions

[c] Emission sources include PM emissions from the mill feed crushing plant and the ore milling and processing plant, and fugitive dust emissions

Figure 8-2 illustrates the relative contributions of the eight source groups to the maximum predicted 24-hour CAC and HCN concentrations at the permanent work camp. Figure 8-3 illustrates the relative contributions of the six source groups to the maximum predicted 24-hour As concentrations at the permanent work camp. The source contribution analysis is presented for each substance of interest below.

NO_2 (NO_X)

The haul trucks are the largest contributor to maximum predicted 24-hour NO_X concentrations at the permanent work camp (HR: 48%) followed by explosives detonation (BL: 40%) and other mining equipment (ME: 12%). Smaller contributors include the access road vehicles (AR: 0.2%) and the PR 391 vehicles (PR 391: 0.07%) with a combined contribution of less than 1%. The ore milling and processing plant (PP) and wind erosion (WE) are not sources of NO_X emissions and therefore, have no contribution to predicted NO_X concentrations.

CO

The explosives detonation is the largest contributor to maximum predicted 24-hour CO concentrations at the permanent work camp (BL: 71%) followed by haul trucks (HR: 20%) and other mining equipment (ME: 9%). Smaller contributors include the access road vehicles (AR: 0.02%) and the PR 391 vehicles (PR 391: 0.01%) with combined contribution less than 1%. The ore milling and processing plant (PP) and wind erosion (WE) are not sources of CO emissions and therefore, have no contribution to predicted CO concentrations.

SO_2

The explosives detonation in the open pit is the largest contributor to maximum predicted 24-hour SO_2 concentrations at the permanent work camp (BL: 96%), followed by haul trucks (HR: 2%) and the ore milling and processing plant (PP: 1%). The other mining equipment (ME: 0.8%), the access road vehicles (AR: 0.01%) and the PR 391 vehicles (PR 391: 0.003%) have a combined contribution of less than 1%. Wind erosion (WE) is not a source of SO_2 emissions and therefore, has no contribution to predicted SO_2 concentrations.

HCN

The ore milling and processing plant is the largest contributor to maximum predicted 24-hour HCN concentrations at the permanent work camp (PP: 80%) followed by the TMF pond (TMF: 20%). The remaining source groups are not sources of HCN emissions and therefore, have no contribution to predicted HCN concentrations.

TSP

The haul roads are the largest contributor to maximum predicted 24-hour TSP concentrations at the permanent work camp (HR: 45%) followed by fugitive dust from mining equipment and material handling

(ME: 27%), the mill feed crushing plant and ore milling and processing plant (PP: 20%) and the access roads (AR: 6%). The remaining three source groups – blasting (BL: 1%), wind erosion (WE: 1%) and PR 391 (PR 391: 0.06%) have a combined contribution of less than 3%.

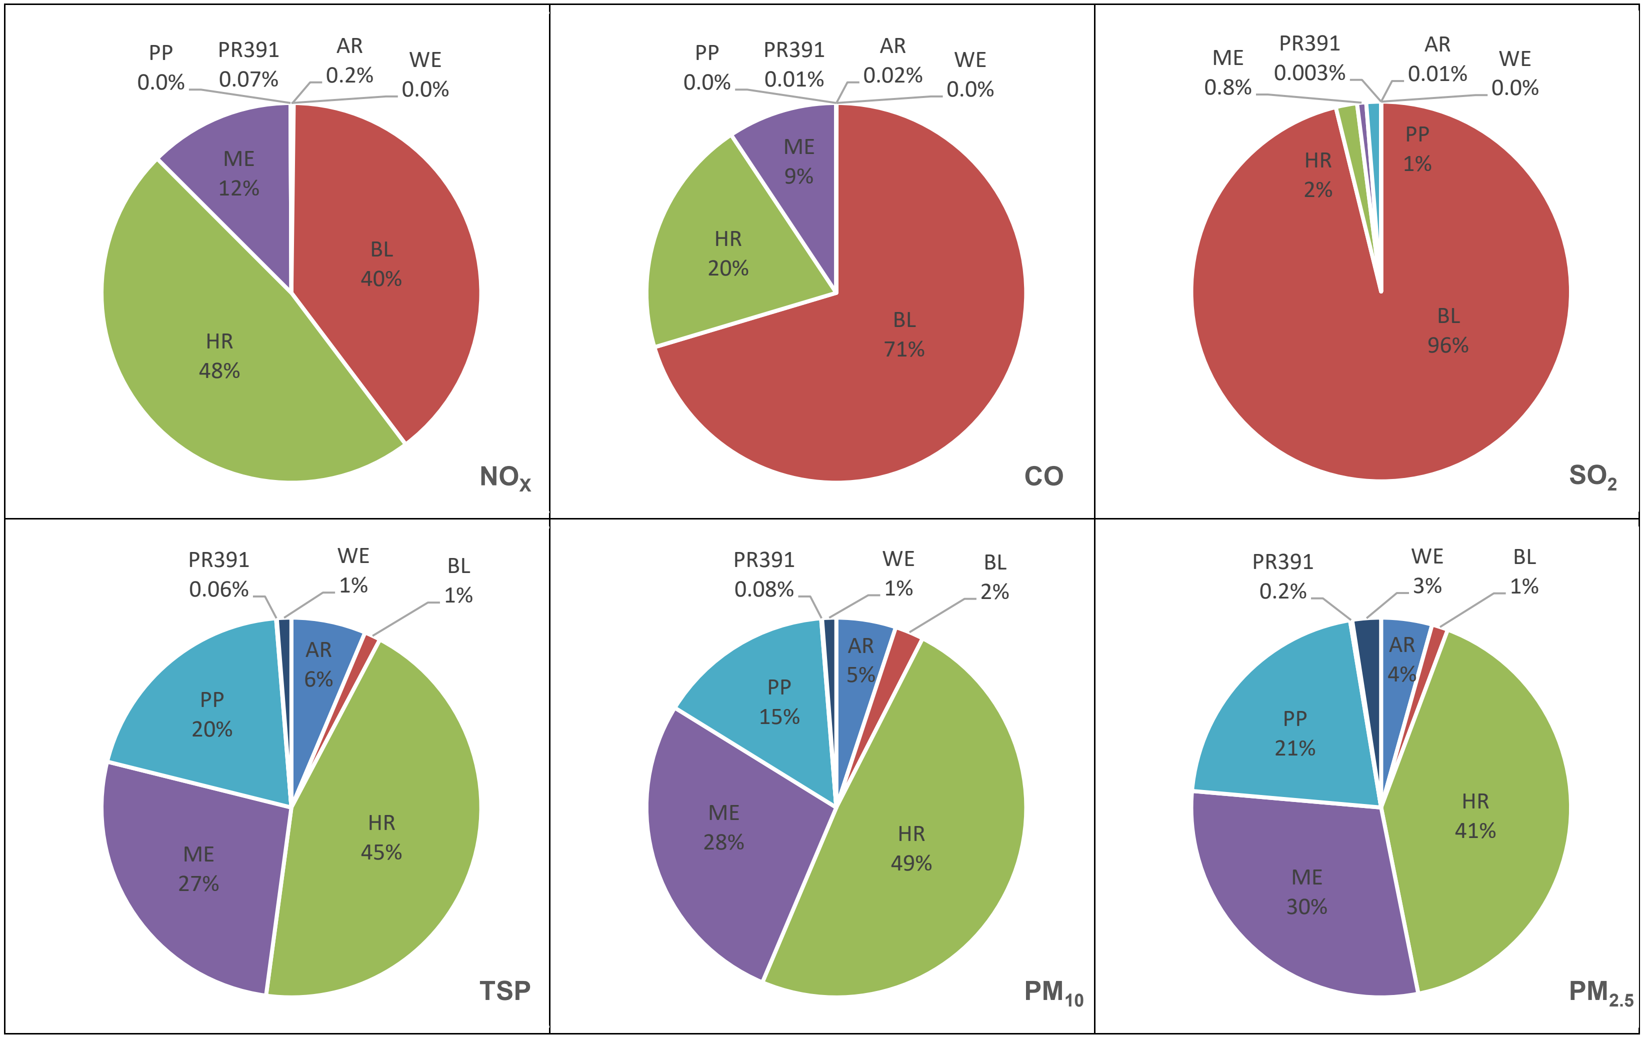

Figure 8-2 Source Contributions to Maximum Predicted 24-hour CAC Concentrations at the Permanent Work Camp at the MacLellan Site

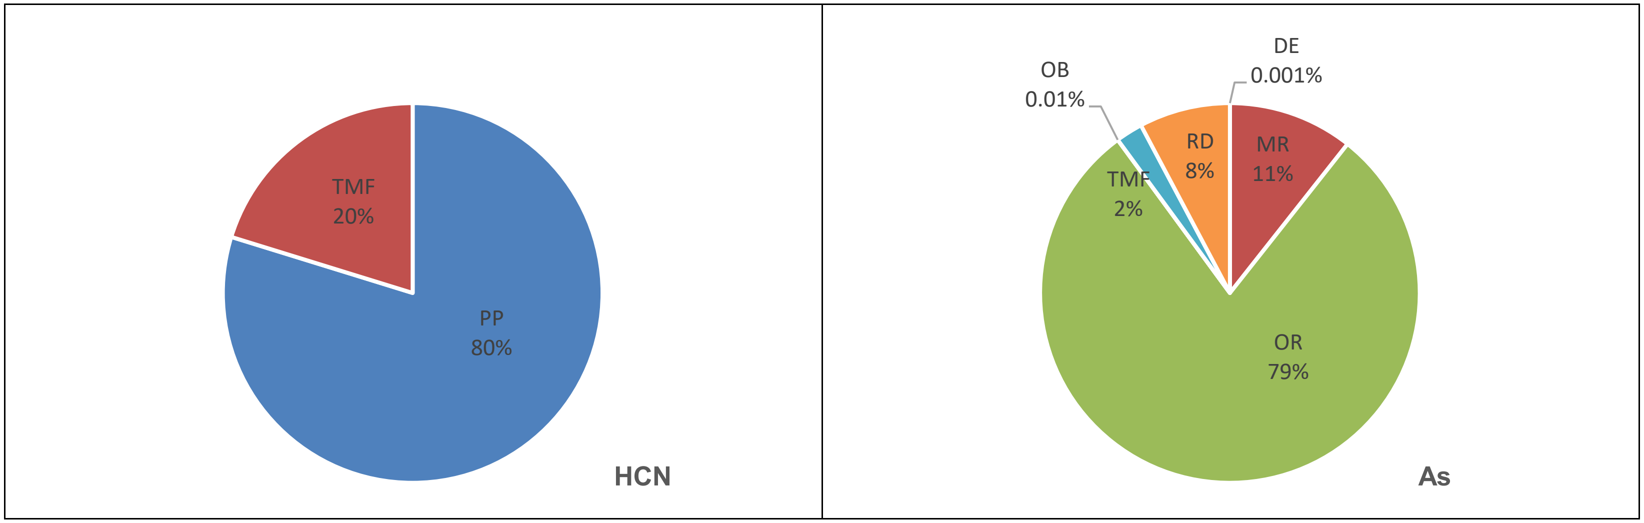

Figure 8-3 Source Contributions to Maximum Predicted 24-hour HCN and As Concentrations at the Permanent Work Camp at MacLellan Site

PM_{10}

The haul roads are the largest contributor to maximum predicted 24-hour PM_{10} concentrations at the permanent work camp (HR: 49%) followed by fugitive dust from mining equipment and material handling (ME: 28%), the mill feed crushing plant and ore milling and processing plant (PP: 15%) and the access roads (AR: 5%). The remaining three source groups - blasting (BL: 2%), wind erosion (WE: 1%) and PR 391 (PR 391: 0.08%) have a combined contribution of less than 3%.

$PM_{2.5}$

The haul roads are the largest contributor to maximum predicted 24-hour $PM_{2.5}$ concentrations at the permanent work camp (HR: 41%) followed by fugitive dust from mining equipment and material handling (ME: 30%), the mill feed crushing plant and ore milling and processing plant (PP: 21%) and the access roads (AR: 4%). The remaining three source groups - wind erosion (WE: 3%), blasting (BL: 1%) and PR 391 (PR 391: 0.2%) have a combined contribution of less than 4%.

As

Ore is the largest contributor to maximum predicted 24-hour As concentrations at the permanent work camp (OR: 79%) followed by mine rock (MR: 11%) and road dust (RD: 8%). The remaining three source groups – tailings (TMF: 2%), overburden (OB: 0.01%) and diesel exhaust (DE: 0.001%) have a combined contribution of less than 3%.

9.0 MODEL PREDICTION UNCERTAINTY

The air quality assessment depends on air quality simulation models to link emissions to air quality changes, and the model predictions depend on the representativeness of the source and emission inventory, the meteorological conditions used in the model, and the algorithms used to represent atmospheric physics and chemistry processes in the models.

9.1 EMISSION UNCERTAINTY

Diesel exhaust emissions from construction and mining off-road equipment are based on the Canadian emission standards for off-road compression-ignition engines (ECCC 2005) and published equipment load factors (US EPA 2010b). Therefore, the level of confidence associated with the estimation of gaseous CAC emissions (e.g., NO_X, CO, SO_2 and VOC) and DPM from these sources is high. The level of confidence for the estimation of emission rates for individual VOC, PAH and metal species is medium because emission factors for these species are derived using a transportation model (MOVES2014a) based on vehicle population distributions built into the model.

Fugitive TSP (and associated PM_{10} and $PM_{2.5}$) emission rates depend on the properties of the surface material, the occurrence and history of surface disturbances, and meteorological conditions. While the air quality assessment uses emission estimation algorithms developed by the US EPA, there is uncertainty associated with estimating these emissions. Particularly, fugitive road dust emissions estimated with the

US EPA emission factors have been found to substantially overpredict PM emissions. This overprediction results in overprediction of the associated ambient TSP, PM_{10} and $PM_{2.5}$ concentrations and dustfall deposition. Multiple investigators have found consistent overpredictions when comparing the predicted fugitive PM concentrations from air quality models to measured PM concentrations, typically by a factor of 2 to 6 (Pace 2005; Countess 2007; Pouliot et al. 2010).

Pace (2005) states that "*Most experts agree that this overestimation is due to a combination of shortcomings in the inventory-modelling process: 1) the multiplier used to "scale" or infer $PM_{2.5}$ from PM_{10} emissions in the inventory, 2) faulty emission factor algorithms, 3) imprecise or difficult to obtain activity data to apply these algorithms (including inability to account for the effect of actual meteorological conditions on emissions), and 4) modelling deficiencies (especially in the treatment of particles near their point of emissions)*".

Practitioners often reduce particulate matter emission rates by a factor between 2 to 6 to account for these issues. In this assessment, fugitive dust emissions estimated using the US EPA approach were used without reduction to obtain a first order understanding of potential magnitude, geographic extent, and frequency of the maximum concentrations in the LAA due to Project operation. Therefore, the PM concentration and deposition predictions should be interpreted as being conservative and overstated.

9.2 METEOROLOGY UNCERTAINTY

The application of five years of hourly meteorological data includes a wide range of conditions which reduces the level of uncertainty related to meteorology. The use of five years of meteorology data is consistent with the recommendations provided in the Guidelines for Air Dispersion Modelling in Manitoba (Manitoba Conservation 2006). The CALMET® model domain for this assessment is relatively flat and therefore, large variations in meteorology across the domain are not expected. The level of confidence related to the meteorological data is rated as moderate to high.

9.3 MODEL UNCERTAINTY

In terms of the air quality model algorithms, the US Environmental Protection Agency (US EPA 2005) states:

> *"Models are reasonably reliable in estimating the magnitude of highest concentrations occurring sometime, somewhere within an area. For example, errors in highest estimated concentrations of ±10 to ±40% are found to be typical, i.e., certainly well within the often-quoted factor-of-two accuracy that has long been recognized for these models."*

In addition, they also state, "*it is desirable to quantify the accuracy or uncertainty associated with concentration estimates used in decision-making. Communications between modelers and decision-makers must be fostered and further developed*."

The US EPA (2005) indicates that the application of regulatory dispersion models is viewed as a best estimate approach and that this approach should be viewed as acceptable to the decision maker. MSD (2006) has issued guidelines for air dispersion modelling recognizing that the modelling is a best estimate approach and to provide consistency with respect to the application of models to assess projects in

Manitoba. The model approach that was used for this assessment is viewed as being a best-practice approach. The level of confidence related to the air dispersion model is rated as moderate to high.

9.4 OVERALL PREDICTION CONFIDENCE FOR CHANGES IN AIR QUALITY

The level of confidence is high for the estimated combustion emissions, the representativeness of the meteorological data, the selected model approach, and the overall effectiveness of the proposed mitigation measures. The prediction confidence associated with the estimation of fugitive dust emissions is medium to low. For this reason, an ambient air quality and meteorology monitoring program would be conducted during construction and operation to determine the effectiveness of fugitive dust mitigation.

10.0 SUMMARY AND CONCLUSIONS

An air quality assessment of the effects of NO_X, CO, SO_2, HCN, TSP, PM_{10}, $PM_{2.5}$ and six metal emissions from the Project was conducted. The air quality assessment evaluated Project emissions separately for the Gordon and MacLellan sites.

The baseline ambient concentrations and dustfall were derived from a combination of local ambient air quality monitoring for $PM_{2.5}$, PM_{10} and dustfall during summer 2015 and summer 2016 and from historical monitoring data from other more distant monitoring stations in Manitoba and Northwest Territories for NO_2, SO_2 and CO, which were not measured during the field programs. The Fort Smith station in Northwest Territories was considered the most representative for the LAA as the station is in a similarly remote area with low population density and with similar meteorological and topographical conditions. The baseline measurements show that baseline air quality in the LAA is very good.

Potential effects on ambient air quality associated with Project operation were evaluated using the CALPUFF® atmospheric dispersion model and the assessment was completed in accordance with the draft Guidelines for Air Dispersion Modelling in Manitoba (Manitoba Conservation, 2006) and guidelines from other provincial jurisdictions. The estimated emissions from Project construction were not modelled because the emissions during the worst-case year of construction were substantially less than emissions from the worst-case (peak production) year of operation at both sites, except for DPM emissions which were 20% higher than the corresponding emissions during operation. The higher DPM emissions during construction are due to the conservative assumption that construction off-road equipment will be mostly rented and will comply with older (Tier 3) Canadian emission standards for off-road diesel engines (ECCC 2005a). If newer (Tier 4) construction off-road equipment is used the DPM emissions during construction will be less. At the Gordon site the construction emissions were 65% to 85% less than the worst-case operation emissions. At the MacLellan site the construction emissions were 20% to 65% less than the worst-case operation emissions. Therefore, the effects on air quality will be less than operation.

The predicted maximum concentrations of gaseous substances (NO_2, CO, SO_2 and HCN) associated with emissions from the Project are below the Manitoba ambient air quality criteria (AAQC) except for maximum predicted 1-hour NO_2, CO and SO_2 concentrations at Gordon site and maximum predicted 1-hour NO_2

concentrations at MacLellan site. However, these occurrences are only predicted to occur on the Project Boundary, are limited to one to two hours per year and are not near sensitive receptors.

The air dispersion modelling indicates exceedances of the 24-hour TSP and PM_{10} AAQC. The predicted TSP and PM_{10} concentrations are strongly influenced by fugitive dust emissions associated with the haul roads. The TSP and PM_{10} predictions are conservative as it has been widely accepted that the US EPA emission factor for fugitive dust from unpaved roads overpredicts the ground-level concentrations by a factor of 2 to 6 (Pace 2005; Countess 2007; Pouliot et al. 2010).

An Air Quality Management Plan (AQMP) will be developed for Project construction and operation to monitor and manage the ambient air quality near the Project. The AQMG will include adaptive management recommendations to reduce fugitive dust emissions and evaluate the need for more rigorous dust mitigation. Monitoring will include meteorological monitoring (wind speed and direction, air temperature and relative humidity and rain precipitation) and ambient PM monitoring (TSP, PM_{10} and $PM_{2.5}$). If the monitoring program indicates that ground-level TSP, PM_{10} and/or $PM_{2.5}$ concentrations are greater than the AAQC, additional mitigation measures to reduce PM emissions will be implemented. Given that dust from the haul roads is the largest source of particulate emissions, more frequent road watering or an application of a dust suppressant will be implemented.

The GHG emissions from the Project construction (i.e., includes the MacLellan site and the Gordon site) are 80,617 tonnes CO_2e per year and are anticipated to be less than 0.011% of national emissions and less than 0.37% of the provincial emissions. The GHG emissions from the Project operation (i.e., includes the MacLellan site and the Gordon site) are 104,885 tonnes CO_2e per year and are anticipated to be less than 0.015% of national emissions and less than 0.48% of the provincial emissions.

13.0 LIMITATIONS

This Technical Modelling Report entitled Lynn Lake Gold Project, Air Quality Impact Assessment was prepared by Stantec Consulting Ltd. ("Stantec") for the account of Alamos Gold Inc. (the "Client") to support the approvals and permitting process for the Lynn Lake Gold Project in Lynn Lake, Manitoba. In connection thereto, this document may be reviewed and used by the federal and provincial government agencies participating in the approvals and permitting process in the normal course of their duties; and stakeholders may provide comment as part of the regulatory approvals process. Except as set forth in the previous sentence, any reliance on this document by any third party for any other purpose is strictly prohibited. The material in it reflects Stantec's professional judgment in light of the scope, schedule and other limitations stated in the document and in the contract between Stantec and the Client. The opinions in contents of the document are based on conditions and information existing at the time the document was published and do not take into account any subsequent changes. In preparing the document, Stantec did not verify information supplied to it by others. Any unauthorized use that a third party makes of this document is the responsibility of such third party. Such third party agrees that Stantec shall not be responsible for costs or damages of any kind, if any, suffered by it or any other third party as a result of decisions made or actions taken based on unauthorized use of this document.

Appendix B CONCEPTUAL MODEL PLAN AND STANTEC RESPONSE MEMORANDUM TO MSD AND ECCC'S REVIEW COMMENTS

Stantec

Memo

To:	Eshetu Beshada, PhD, P.Eng. Manitoba Sustainable Development Environmental Approvals 160 – 123 Main Street Winnipeg, Manitoba, R3C 1A5	From:	Inna Yankova Air Quality Scientist Calgary (25th St) AB Office Daniel Jarratt Atmospheric Discipline Lead Calgary (25th St) AB Office
Project Number:	111473000	Date:	June 20, 2017

Reference: Air Quality Dispersion Modelling Plan for the Lynn Lake Gold Project

1.0 CONCEPTUAL MODEL PLAN

Project Name:	Lynn Lake Gold Project (LLGP, the "Project")
Company:	Alamos Gold Inc. (Alamos)
Location (m E, m N, UTM Zone):	396,775 m E; 6,302,500 m N, UTM Zone 14 (NAD83)
Air Quality Consultant:	Stantec Consulting Ltd. (Stantec)
Air Quality Consultant Contacts:	Inna Yankova, Air Quality Scientist Daniel Jarratt, Senior Air Quality Scientist, Atmospheric Discipline Lead
Project Overview:	The LLGP is the proposed redevelopment of two historical gold mines near Lynn Lake, Manitoba. The LLGP consists of two primary deposit sites: the MacLellan site and the Gordon site, located approximately 30 km apart. Alamos intends to construct (redevelop), operate and close/reclaim the gold mines at both historical sites. The MacLellan site was formerly operated as an underground gold and silver mine. The Gordon site was formerly operated as an open pit mine with two open pits (Wendy Pit and East Pit) with depths 60 m and 73 m, respectively. Alamos proposes to develop new open pits at both sites: an open pit with a depth of 360 m at MacLellan site, and an open pit with a depth of 200 m at Gordon site encompassing the two smaller historical open pits. The peak combined production rate from both mines will be approximately 27 megatonnes of total mine excavation per year (Mt/a), with a design mill feed rate of 7 kilotonnes per day (ktpd). The expected mine life is approximately 11 years in addition to the construction and preproduction period of two years. The mine operation is scheduled for 365 days per year

Reference: Air Quality Dispersion Modelling Plan for the Lynn Lake Gold Project

with two 10-hour shifts per day.

Alamos proposes to add new mine infrastructure at the MacLellan and Gordon sites. The MacLellan site will include a new open pit, low grade stockpiles, mine rock storage areas, Run-of-Mine (ROM) stockpiles, a central ore mining and processing plant, associated plant infrastructure, a new 2.6 km access road, and a Tailings Management Facility (TMF). Infrastructure at the Gordon site will be limited to the new open pit, low grade ore stockpiles, mine rock storage areas, and minor supporting infrastructure for equipment storage and maintenance. There will be no processing plant at the Gordon site; the ore will be transported to the MacLellan processing plant via Provincial Road (PR) 391 connecting both sites (Figure 1 in Attachment A). Power will be supplied to the mining operations at the Gordon site via a diesel-powered generator. Power will be provided to the MacLellan site via Manitoba Hydro.

Alamos has retained Stantec to conduct an environmental assessment (EA) of the proposed Project. Air Quality will be a Valued Component (VC) of the EA. The air quality assessment will be conducted in accordance with the draft Guidelines for Air Dispersion Modelling in Manitoba (Manitoba Conservation 2006) using the CALMET-CALPUFF dispersion model.

This document is presented to inform Manitoba Sustainable Development about the proposed dispersion modelling approach for this air quality assessment. Approval of this dispersion modelling plan will provide Stantec and Alamos with assurance that the methodology proposed will meet Manitoba Sustainable Development requirements for environmental approvals.

Emission Sources:

The air quality assessment will be conducted for the worst-case year of mine operation meaning the operation that will result in maximum releases of air contaminants to the atmosphere. The worst-case year is selected using the maximum production rate, maximum material movement and maximum diesel fuel usage. The worst-case year for emissions from the Gordon site and ROM ore haulage on PR 391 is Year 3 of operation. Year 6 of operation is selected as the worst-case year for emissions from the MacLellan site, based on maximum production rate, material movement and diesel usage at the site. Year 3 emissions from the Gordon site and PR 391, and Year 6 emissions from the MacLellan site will be combined in one air dispersion model to conservatively represent worst-case emissions for the

Project.

The emission sources for the Project being assessed are typical for an open pit mine. Emissions from the following sources will be estimated and included in the air dispersion model:

- Drilling and blasting
- Diesel combustion exhaust emissions from off-road mining equipment and haul trucks
- Diesel combustion exhaust emissions from the generator at the Gordon site
- Fugitive dust emissions from operation of the off-road mining equipment
- Fugitive dust emissions from truck loading and unloading
- Fugitive dust emissions from material transfer on conveyors and stockpiles
- Mechanically generated dust emissions by haul trucks along mine haul roads
- Mechanically generated dust emissions by haul trucks on PR 391
- Mechanically generated dust emissions on access roads
- Fugitive dust emissions from wind erosion on stockpiles
- Fugitive dust emissions from wind erosion on TMF dry banks
- Emissions from three process plant stacks (e.g., baghouse at the primary crusher, wet scrubber at the secondary crusher, baghouse at the gold room)

Emission Estimation Methods:

Emissions for the Project will be based on engineering design and feasibility studies. The emission rates will be estimated using emission standards for off-road diesel engines and published emission factors. Emission factors will be primarily adopted from the U.S. EPA AP-42 emission factors database. It is assumed that a new mine fleet complying with Tier 4 emission standards (ECCC 2005) will be utilized for the Project. Tier 4 standards refer to the more stringent emission standards for off-road diesel engines that are manufactured in or after 2014.

Modelling Scenarios:

Project emissions will be modelled for two cases:

- Project Case: emissions from the Project alone, associated with Year 6 of operation for the MacLellan site, Year 3 of operation of the Gordon site and Year 3 of operation for haul truck traffic on PR 391.
- Application Case: emissions for the Project Case in addition to background ambient concentrations representing other natural and anthropogenic emissions sources that have not

been directly included in the dispersion modelling.

Air emissions from the Project during the construction and pre-production phase (2 years) will not be modelled because these are expected to be short term in duration, substantially lower in magnitude than operation (11 years), and not result in any substantive effects on air quality.

Substances of concern:

The air quality assessment will include the Criteria Air Contaminants (CACs) and total particulate deposition (i.e. dustfall). In addition, ambient concentrations and deposition of metals will be modelled and included in the assessments of human health and ecological risk, and vegetation, both separate VCs of the EA. The substances that will be included in the air dispersion model are as follows:

- Total suspended particulates (TSP), assumed to be comprised of particles with aerodynamic diameter less or equal to 30 µm
- Coarse particulate matter with particle aerodynamic diameter less or equal to 10 µm (PM_{10})
- Fine particulate matter with particle aerodynamic diameter less or equal to 2.5 µm ($PM_{2.5}$)
- Nitrogen dioxide (NO_2)
- Carbon monoxide (CO)
- Sulphur dioxide (SO_2)
- Total particulate deposition (i.e. dustfall)
- Metals
- Metals deposition

Particulate Matter (PM) will be divided into five PM substances: diesel PM, ore PM, waste rock PM, tailings PM and surface dust PM. The three PM substances will be modelled separately in the air dispersion model and will be evaluated separately in the human health environmental assessment. Polycyclic aromatic hydrocarbons (PAHs) and volatile organic compounds will not be included in the modelling because there are no substantial sources that would result in measurable air quality effects.

Model domain and receptors:

Figure 1 in Attachment 1 illustrates the proposed 50 km by 28 km study area and the location of the MacLellan and Gordon sites. For the assessment, the Project Development Area (PDA) boundary is defined as an outline around the active development areas at each mine site, with a buffer of 100 m. Public access will likely be restricted at the PDA boundary.

A nested grid of receptors following the spacing requirements in

Reference: Air Quality Dispersion Modelling Plan for the Lynn Lake Gold Project

the Draft Guidelines for Air Dispersion Modelling in Manitoba (Manitoba Conservation 2006) and the Air Dispersion Modelling Guideline for Ontario (MOECC 2016) will be used in the model:

- 20 m spacing along the PDA boundary and in the areas of maximum impact
- 50 m spacing within 500 m of the PDA boundary
- 100 m spacing within 1.3 km of the PDA boundary
- 200 m spacing within 2.1 km of the PDA boundary
- 500 m spacing within 6.9 km of the PDA boundary
- 1,000 m spacing beyond 6.9 km of the PDA boundary

The locations of residences, traditional land use sites and vegetation samples will be included as special receptors in the dispersion model. Table 1 in Attachment 2 lists the 252 special receptors that will be included in the air dispersion model in addition to the locations in the nested receptor grid. Stantec can include additional special receptors identified by Manitoba Sustainable Development, if required.

Terrain characteristics:

The terrain within the 50 km by 28 km study area is relatively flat ranging from approximately 280 m above mean sea level (m ASL) in the southeast corner of the study area to 380 m ASL at the northwest corner of the study area. The Canadian Digital Elevation Model (CDEM) data obtained from GeoGratis (NRCan 2012) will be used to determine the terrain characteristics in the study area.

Dominant land cover:

The land cover within the study area is mostly comprised of forest and lakes, referred to as Undeveloped Rural (A4) and Water Surface (A5) land use types, respectively, based on Manitoba Sustainable Development's standard land use type classification (Manitoba Conservation 2006).

Existing ambient air quality:

The Project is located near Lynn Lake in Northern Manitoba. The closest ambient monitoring station is in Thompson Manitoba, located approximately 230 km southeast of Lynn Lake. The Thompson monitoring station measures SO_2, PM_{10} and $PM_{2.5}$. Due to lack of continuous monitoring near the Project, a field ambient monitoring program was conducted in the summer of 2015 and 2016. During the field program, measurements were made for: $PM_{2.5}$, PM_{10} and dustfall as well as metals in dustfall.

The monitoring results during the field program provide sufficient information to characterize the existing ambient concentrations of $PM_{2.5}$, PM_{10}, and dustfall, and metals deposition in the Project region because there are no large industrial sources nearby and ambient concentrations are relatively constant. Baseline ambient concentrations of the other substances of concern (NO_2, CO, SO_2 and metals) will be based on ambient monitoring in more distant (but like the Project setting) regions and on published reports for typical values in remote northern areas. Stantec is requesting guidance from Manitoba Sustainable Development on appropriate baseline data to be used for the Project.

Meteorological data: Stantec will create mesoscale meteorological data using the National Center for Atmospheric Research (NCAR) Weather Research and Forecasting (WRF) mesoscale model (NCAR, 2017) for the region around the Project with a spatial resolution of 12 km for a five-year period (2012-2016). This data will be used as input into the CALMET meteorological model (Scire, J.S. et. al 2000a) to provide site-specific 3-dimensional meteorology field with a finer horizontal grid spacing of 500 m for the CALPUFF dispersion model. The CALMET model domain will encompass the 50 km by 28 km CALPUFF model domain with a buffer of 10 km on each side. In addition to WRF data, CALMET will incorporate surface observations from one of the two Environment and Climate Change Canada (ECCC) Lynn Lake weather stations (nos. 5061645 and 5061649), whichever one has the most complete records. There are no upper air stations within the CALMET model domain. Therefore, upper air data from WRF will be used. The latest version of CALMET at the time of the assessment will be used, the most current is version 6.5.0. The meteorological modelling will follow the recommendations in the models' documentation.

Stantec has used mesoscale modelling data as input into CALMET for several years. In some jurisdictions in Canada, it has become the standard method for creating meteorological data for dispersion models (Ontario, Alberta, British Columbia, Saskatchewan) and has been accepted by the U.S. EPA (U.S. EPA 1998).

Dispersion model: Stantec will carry out the air dispersion modelling using the latest version of the CALPUFF model (Scire, J.S. et al. 2000b) at the time of the assessment, the most current is version 7.2.1. The CALPUFF model domain coincides with the study area (50 km by 28 km). The CALPUFF model setup will follow the recommendations of the Draft Guidelines for Air Dispersion Modelling in Manitoba (Manitoba Conservation 2006). In the absence of specific requirements in the Manitoba Guidelines, the dispersion modelling will follow the Air Dispersion Modelling Guideline for Ontario (MOECC 2016) and the recommendations in the model documentation.

The latest version of the model at the time that the assessment starts will be used. If a newer version is released during the assessment, Stantec will discuss with Manitoba Sustainable Development if any remodelling is required using the updated version.

Ambient air quality criteria: Attachment 3 lists the Manitoba Ambient Air Quality Criteria (Manitoba Sustainable Development 2005) for the substances of concern. The Manitoba ambient objective for $PM_{2.5}$ is based on the former Canada-Wide Standard (CWS) of 30 µg/m³ for 24-hour averaging period. The CWS has been replaced by the Canadian Ambient Air Quality Standards (CAAQS). The new CAAQS for $PM_{2.5}$ (CCME 2012) are more stringent than the CWS. Therefore, the CAAQS for $PM_{2.5}$ are proposed for the assessment. Stantec understands that the CAAQS for SO_2 are intended for regional planning and management activities and do not represent air standard limits by individual facilities at the provincial level.

Six metals have Manitoba ambient criteria. Predicted ambient metal concentrations will be assessed against these criteria. Predicted concentrations for all metals will be provided for the human health and ecological risk assessment.

As dustfall does not have corresponding Manitoba criterion, the criteria from Ontario (MOECC 2012) are proposed. If Manitoba Sustainable Development has a preferred alternate criterion for dustfall, Stantec will provide model predicted results compared to that criterion.

2.0 CLOSURE

This conceptual modelling plan has been prepared based on Stantec's understanding of the Draft Guidelines for Air Dispersion Modelling in Manitoba and modelling guidance from other jurisdictions. Should you have any questions or require further information, please contact Daniel Jarratt at (403) 441-5064 or email Daniel.Jarratt@stantec.com.

Stantec

Memo

To:	Eshetu Beshada, PhD, P.Eng. Manitoba Sustainable Development (MSD) and Brian Asher, Environment and Climate Change Canada (ECCC)	From:	Inna Yankova, Yan Shen and Daniel Jarratt, Stantec Consulting Ltd.
File:	111473008	Date:	July 16, 2019

Reference: Comments on the Air Quality Dispersion Modelling Plan for the Lynn Lake Gold Project Environmental Assessment

The Atmospheric Environment team at Stantec Consulting Ltd. (Stantec) received comments from the Manitoba Sustainable Development (MSD) and Environment and Climate Change Canada (ECCC) on June 28, 2019 related to the air quality dispersion modelling plan (Modelling Plan) for the Environmental Assessment related to the proposed Lynn Lake Gold Project (LLGP, the “Project”) in Northern Manitoba.

This memorandum provides Stantec’s responses to the MSD and ECCC’s review comments.

1. **MSD Comment:**
   What is the rationale of using CALPUFF?

Stantec Response: The LLGP consists of two primary deposit sites: the MacLellan site and the Gordon site, located approximately 30 km apart. The proposed air quality study area encompasses the two mine sites with an extent of 50 km in the east-west directions by 28 km in the north-south directions.

The CALPUFF model (Scire et al. 2000) is a multi-layer, multi-species, non-steady state puff dispersion model that can simulate the effects of time and space-varying meteorological conditions on substance transport, transformation, and removal. CALPUFF contains algorithms for near-source effects such as building downwash, transitional plume rise, partial plume penetration, as well as long-range effects such as chemical transformation, and pollutant removal (dry deposition and wet scavenging).

CALPUFF was selected for the air quality assessment based on the following considerations:

- As a puff dispersion model, CALPUFF is better suited (compared to plume dispersion models such as AERMOD) to simulate long-range transport and dispersion in the relatively large study area (50 km by 28 km) and the potential overlapping effects of emissions from the two mine sites located approximately 30 km apart.
- CALPUFF can utilize a time varying 3-dimensional wind field.
- CALPUFF can estimate dry and wet deposition of gases and particulate matter (PM).
- CALPUFF has the capability to model multiple species in one model simulation.

Stantec has recently used CALPUFF in environmental impact assessments (EIA) for mining and construction projects, including the EIA for the Hope Bay gold mine project (TMAC Resources) in Nunavut and the EIA for the Springbank Off-Stream Reservoir construction project west of Calgary, Alberta for Alberta Transportation.

Reference: Comments on the Air Quality Dispersion Modelling Plan for the Lynn Lake Gold Project Environmental Assessment

2. **MSD Comment:**
   Will the modeled mesoscale meteorological data using WRF model be compared with any nearby observational data before input to CALMET meteorological model?

Stantec Response: A comparison is provided in Attachment A. The figures in Attachment A illustrate the similarities and small differences between the modeled mesoscale meteorological data using the WRF model and meteorological observations from the Lynn Lake Airport monitoring station operated by Environment and Climate Change Canada (ECCC) for five years (2012-2016).

3. **MSD Comment:**
   Upper air data might be available at The Pas, MB which is approximately 300 km south of Lynn Lake. Was this data being considered to validate the met data?

Stantec Response: The upper air data from the meteorological monitoring station in The Pas, MB are not planned to be used to validate the WRF and CALMET simulations for meteorology that will be used by CALPUFF to predict ground-level concentrations. The reasons are for this are provided below.

1. The La Pas upper air meteorological monitoring station is outside the LLGP EA air quality model domain.
2. The draft Guidelines for Air Dispersion Modelling in Manitoba (Manitoba Conservation 2006) do not provide specific guidance for the use of upper air data and the CALMET model setup. Hence, the guidance provided in the Alberta Environment and Parks (AEP) Air Quality Model Guideline (AEP 2013) was followed with respect to the use of upper air data and the CALMET model setup. The AEP Air Quality Model Guideline requires all applications use MCLOUD=4 to calculate cloud cover data from the WRF model output (relative humidity and pressure fields at all WRF levels), therefore, for consistency, it would be more beneficial to use the upper air data from WRF model output.

4. **MSD Comment:**
   In the absence of representative air quality data in Manitoba, AQ suggests to use air quality data outside of the province that is comparable with Lynn Lake. (example, remote location and has similar meteorological and topographical conditions).

Stantec Response: Baseline ambient air concentrations of $PM_{2.5}$, PM_{10} and dustfall as well as baseline metals deposition will be derived based on ambient measurements taken during the field program in 2015 and 2016. Baseline ambient concentrations of NO_2, SO_2 and CO will be based on ambient monitoring data from more distant monitoring stations in a similar remote location and with similar meteorological and topographical conditions. The baseline ambient ground-level concentrations for NO_2, SO_2 and CO will be referenced from the Wanipigow Sand Extraction Project located in a remote area approximately 160 km northeast of Winnipeg and approximately 700 km southeast of the LLGP. The Wanipigow Sand Extraction project received its Environmental Act License No. 3285 from Manitoba Sustainable Development on May 16, 2019. The baseline concentrations for NO_2, SO_2 and CO will be included in the LLGP EA along with the rationale for the selection of the baseline concentrations.

5. **ECCC Comment:** Proposed Ambient Air Quality Criteria
   ECCC requests that predicted ambient concentrations around the project be compared to the most stringent standard available. The Canadian Ambient Air Quality Standards (CAAQS) for nitrogen dioxide were introduced in December 2017 and are more stringent than the Manitoba Ambient Air Quality Criteria proposed in Table 2 of the Conceptual Model Plan. ECCC requests Alamos compare predicted NO_2 concentrations to the 2025 CAAQS at the 1-hour (42 ppb) and annual (12 ppb) timeframes. Similarly, the CAAQS for sulphur dioxide in Table 2 is the 2020 version of the standard. Since the project is expected to be in operation beyond 2025, ECCC requests that the 2025 standards be used, 65 pb (1-hour) and 4 ppb (annual).

Stantec Response: The Canadian Ambient Air Quality Standards (CAAQS) were developed as part of the Air Quality Management System (AQMS; CCME 2012a) with the objective of driving continuous improvement of air quality in Canada. The Canadian Council of Ministers of the Environment (CCME) describes the process for selecting monitoring stations, measuring pollutant concentrations and determining achievement of the CAAQS (CCME 2012b, CCME 2012c). Determining achievement of the CAAQS is based upon using measured air quality concentrations at community monitoring stations and comparing the measured levels to the CAAQS and assigning air quality status to one of four management levels (CCME 2012b, CCME 2012c). The four air quality management levels require progressively more rigorous actions by jurisdictions as air quality approaches or exceeds the CAAQS, thereby ensuring proactive management actions are undertaken to reduce emissions and prevent exceedances of the CAAQS (CCME 2012b).

CCME guidance on determining achievement of the CAAQS states that the monitoring stations that are used to determine achievement and guiding air quality management efforts should be located in areas that reflect air quality where people live (CCME 2012c). The CCME has developed guidance for $PM_{2.5}$ (CCME 2012c), however, has not yet released the Guidance on determining achievement of the NO_2 CAAQS. The guidance for $PM_{2.5}$ states that the monitoring sites should not, however, be sited near or unduly influenced by a nearby emission source (CCME 2012c). For example, Section 3.2 of the Guidance Document on Achievement Determination Canadian Ambient Air Quality Standards for Fine Particulate Matter and Ozone states that monitoring stations should not be located in close proximity to the fence line of an industrial facility or next to a major roadway (CCME 2012c).

The CCME's guidance suggests that the CAAQS are intended to be used in conjunction with results from the air quality modelling to predict the effect of the project on downwind locations such as communities and other sensitive receptors and are not intended to be used as standards to achieve compliance at the project fence line (e.g., perimeter). Following the CCME's guidance (CCME 2012b, CCME 2012c), the LLGP model predicted NO_2 and SO_2 concentrations at 203 human receptors out of 252 special receptors identified for the Project that represent communities, locations of residences and traditional land use sites will be compared to the 2025 CAAQS in the EA. The remaining 49 (252 – 203) special receptors are locations of vegetation samples.

6. **ECCC Comment:** Additional emission sources
Some additional combustion sources were not included in the list of emission sources, including light duty vehicles on haul roads and access roads, as well as incinerators. In addition, light duty vehicles are also a source of fugitive dust. ECCC requests that these additional emission sources be included in the model.

Stantec Response: In addition to the emission sources listed in the modelling plan, emissions from the following sources will be estimated and included in the dispersion model:

- Tailpipe exhaust emissions from light duty vehicles on haul roads and access roads
- Fugitive dust emissions generated by light duty vehicles traffic along the haul roads and access roads

There are no proposed incinerators for the Project.

7. **ECCC Comment:** Modelling Scenarios
The base case is not explicitly listed as one of the model scenarios. ECCC requests that Alamos clarify whether a base case will be modelled, and its predicted concentrations compared to the Project and Application cases.

Stantec Response: A Base Case will not be modelled as there are no existing or proposed industrial developments within the air quality study area. There were no existing substantial sources of air and noise emissions during the field program that Stantec conducted in 2015 and 2016. Due to the Project restart in 2019, Stantec inquired with the Town of Lynn Lake and received a confirmation letter (Town of Lynn Lake Letter, May 13, 2019) stating that there have been no new substantial sources of air and noise emissions (e.g. commercial, residential, industrial) since 2016.

The baseline ambient air quality will be characterized by representative ambient concentrations that will account for other more distant natural and anthropogenic sources that have not been directly modelled. For the Application Case, the baseline concentrations will be added to maximum model predicted concentrations for the Project and compared to the Manitoba Ambient Air Quality Criteria (MSD 2005).

8. **ECCC Comment:** Construction Emissions
Construction emissions were not included as a model scenario as the associated emissions were stated to be substantially lower than operational emissions. ECCC requests that emissions from construction be quantified and compared to project emissions to demonstrate that construction emissions do not need to be modeled.

Stantec Response: The mine plan for the Project includes two (2) years of construction and pre-production. Construction emissions will be estimated for the construction and pre-production year that will result in maximum releases of air contaminants to the atmosphere. In taking this conservative approach, the representative worst-case construction year will be selected upon consideration of the maximum diesel fuel usage, maximum material movement and maximum pre-production rate (e.g., tonnes of waste and overburden material moved). The total annual construction and pre-production emissions for the worst-case construction year will be compared with the total annual Project emissions to demonstrate that construction emissions do not need to be modelled.

The next two items are not in response to comments received from MSD and ECCC. These two additional points provide additional information about potential air quality modelling concerns that are associated with the latest version of the mine plan (e.g., inclusion of a worker's camp) and the proposed methodology for the determination of terrain characteristics for the air dispersion model.

9. **Stantec Comment:** Additional information regarding Substances of Concern

The original modelling plan lists the substances of concern that will be included in the air dispersion model that includes the Criteria Air Contaminants (CACs), dustfall, metals and metals deposition. One of the proposed changes to the Project is the construction of a worker's camp within the project development area (PDA) of the MacLellan site. The workers camp will be included as a special receptor for the human health risk assessment (HHRA) that will evaluate potential effects of changes to air quality and health health on off-duty workers living in the camp. The air quality assessment will expand the list of modelled substances to include individual volatile organic compounds (VOCs) and polycyclic aromatic hydrocarbons (PAHs) from tailpipe diesel exhaust to support the HHRA for the EA.

10. **Stantec Comment:** Additional information regarding Terrain Characteristics

The original modelling plan states that the Canadian Digital Elevation Model (CDEM) obtained from GeoGratis will be used to determine terrain characteristics in the study area. The CDEM data has a spatial resolution of approximately 30 m.

In 2015, ATLIS Geomatics was contracted by Stantec to conduct an aerial survey to acquire Light Detection and Ranging (LiDAR) data over Lynn Lake area of approximately 141 km². This LiDAR data set has a high spatial resolution of approximately 5 m and was used to extract in-pit and off-pit terrain elevations during the development of the mine plan for the Project. The LiDAR data, however, covers only the MacLellan and Gordon mine sites. In order to use the high-resolution LiDAR data for the air quality assessment, Stantec integrated the LiDAR data with Shuttle Radar Topography Mission (SRTM) data obtained from the U.S. Geological Survey (USGS) 3D Elevation Program. The SRTM data has spatial resolution of approximately 30 m and was integrated seamlessly with the LiDAR data. Initially, Stantec attempted to merge the LiDAR data with CDEM data but there were vertical differences of up to 10 m in some locations.

Stantec proposes to utilize the integrated LiDAR and SRTM data to determine terrain characteristics in the study area for the air quality assessments. The SRTM has the same spatial resolution as the CDEM and can be integrated seamlessly with the LiDAR data. Figure 1 in Attachment B shows the terrain elevations in the air quality study area based on the integrated LiDAR and SRTM digital elevation data.

ATTACHMENT A

COMPARISON OF MODELLED MESOSCALE METEOROLOGICAL DATA TO NEARBY OBSERVATIONAL DATA

ATTACHMENT A: COMPARISON OF MODELED MESOSCALE METEOROLOGICAL DATA TO NEARBY OBSERVATIONAL DATA

The meteorological observations from the Environment and Climate Change Canada (ECCC) Lynn Lake Airport station were used to determine the representativeness of the mesoscale meteorological data, generated using the Weather Research and Forecasting (WRF) model. The coordinates of the ECCC Lynn Lake Airport station and nearest WRF grid point are provided in Table A-1. The selected WRF grid point is located approximately 5 km west of the ECCC Lynn Lake Airport station. Wind speed, wind direction and temperature data at the lowest vertical level in the model were extracted from WRF and compared to the ECCC Lynn Lake Airport observations for a five-year period (2012 to 2016).

Figure A-1 compares the wind roses generated for the ECCC Lynn Lake Airport to the WRF model predictions from the nearest WRF grid point. As shown, there is general agreement between the measured (ECCC) and predicted (WRF) wind roses, in that the predominant (most frequent) winds are from northwest, west, north and east. Further, the wind speed class frequency distributions are also in reasonable agreement, in that the most frequent wind speed class is 2.0 to 4.0 m/s.

Figure A-2 compares the monthly average surface air temperatures from the WRF model predictions to measurements at the ECCC Lynn Lake Airport station. The WRF model predictions show warm bias during November, December, January and February; however, there is a reasonable agreement with the ECCC Lynn Lake Airport observations throughout the five-year period.

Since the measured values and the WRF model predictions are in reasonable agreement at the Lynn Lake Airport station (within the CALMET model domain) and close to the Project site, the WRF model predictions are reasonably representative of meteorological conditions in the model domain. As a result, the simulated meteorological data from the CALMET model are suitable for use in the CALPUFF model to predict ground-level concentrations for the Lynn Lake Gold Project Environmental Assessment.

Table A-1 Coordinates of Lynn Lake Airport Surface Station (ECCC) and Nearest WRF Grid Point

Location Name	UTM east (m)	UTM north (m)	UTM zone	Latitude (N)	Longitude (W)

Appendix C PROJECT OPERATION AND CONSTRUCTION EMISSIONS INVENTORY

C.1 INTRODUCTION

To assess the air quality effects associated with the Lynn Lake Gold Mine (the Project) construction and operation, an emissions inventory described in this Appendix is used in combination with a dispersion model to predict air contaminant concentrations at ground level in the Local Assessment Area (LAA) due to Project emissions.

C.1.1 SUBSTANCES OF INTEREST

The air quality assessment focuses on criteria air contaminants (CACs) that can potentially cause harm to human health, the environment, and property. These substances are called CACs because the Manitoba Government, and Environment and Climate Change Canada have ambient air quality criteria, guidelines, or standards for these substances. CACs of interest for this Project are:

- sulphur dioxide (SO_2)
- nitrogen oxides (NO_X)
- carbon monoxide (CO)
- particulate matter with aerodynamic diameter less or equal to 2.5 µm ($PM_{2.5}$)
- particulate matter with aerodynamic diameter less or equal to 10 µm (PM_{10})
- total suspended particulates with aerodynamic diameter less or equal to 30 µm (TSP)
- volatile organic compounds (VOC)
- Hydrogen Cyanide (HCN)

The gaseous CACs (NO_X, SO_2, CO, VOC), $PM_{2.5}$, PM_{10}, and TSP are associated with exhaust emissions from mining equipment. Fugitive dust emissions from surface disturbance activities result in particulate matter emissions of various sizes (e.g. $FPM_{2.5}$, FPM_{10}, and FTSP). Although not considered a CAC, total particulate matter deposition (dustfall) is a criteria often evaluated for mining operations for the accumulation of particulate matter on soils. HCN emissions will occur from the carbon-in-pulp adsorption tanks due to volatilization losses of sodium cyanide (NaCN) used in the leach and adsorption train.

This air quality assessment includes specific VOC, polycyclic aromatic hydrocarbon (PAH) and metal substances. VOCs and PAHs result from mining equipment exhaust. Trace amounts of metals are in mining equipment exhaust and are also carried on windblown dust. Emission rates have been estimated for ten (10) VOCs, sixteen (16) PAH compounds and twenty (20) metal substances. Of these, there are ambient air quality criteria for 7 VOCs, 2 PAHs and 6 metals which are considered for air quality assessment and the others were included as requested for the human health assessment. The predicted concentrations and depositions for the 10 VOC, 16 PAHs, and 20 metal substances are provided to the human health assessment team.

C.1.2 DISPERSION MODEL CONTEXT

Maximum representative hourly and daily average substance emission rates are required for the dispersion model assessment. Ambient concentration predictions associated with maximum hourly emission rates were compared to short-term ambient criteria based on averaging periods shorter than a day (e.g., 1-hour, 8-hour). Ambient concentration predictions associated with daily average emission rates were compared to ambient criteria based on averaging periods greater than 8-hour (e.g., 24-hour, 30-day and annual).

C.1.3 EMISSION FACTOR AND EMISSION RATE UNITS

In the following sections, emission factors and emission rates are presented in mixed metric and imperial units because most emission factors used for emission estimation originate from the US EPA AP-42 Fifth Edition Compilation of Air Pollutant Emission Factors (US EPA, 1998), which are in imperial units.

The emissions from mine activities are estimated for three emissions scenarios:

- Hourly Emission Rates—the worst-case maximum emission rates that may occur during any given hour of the mine operation. For the estimation of maximum hourly emissions, a 100% utilization of the mine vehicle fleet is assumed.
- Daily Emission Rates—average daily emission rates considering actual daily mine fleet utilization which will be less than 100%.
- Annual Emission Rates—average annual emission rates considering actual annual mine fleet utilization which will be less than 100%

The emissions summaries are presented in metric units (e.g., g/s, kg/d, and t/y). The emissions summaries presented in the following sections show the maximum hourly and daily average emission rates in units of grams per second (g/s) for direct input to the dispersion model.

To illustrate the total emissions for those time intervals (hour, day, year) the emission summaries are presented in kilograms per hour (kg/h) for total hourly emissions, in kilograms per day (kg/d)—for total daily emissions, and in tonnes per year (t/y)—for total annual emissions.

C.2 EMISSION FACTORS

This section presents the emission factors for heavy duty diesel engines, explosive detonations, power generation, the temporary mobile crushing plant and fugitive dust emissions as well as the emission rate calculation methodology for point sources associated with the Project. The temporary mobile crushing plant is used only during Project construction.

C.2.1 DIESEL EXHAUST EMISSIONS: CRITERIA AIR CONTAMINANT EMISSION FACTORS

C.2.1.1 Off-Road Diesel Exhaust Emission Factors

Exhaust emissions from off-road diesel equipment are based on the Canadian off-road compression-ignition engine emission standards (ECCC, 2005) developed under the authority of the Canadian Environmental Protection Act (CEPA). The Canadian Off-Road Compression-Ignition Engine Emission Regulations (ECCC, 2005) mirror the corresponding U.S. Code of Federal Regulation (CFR; (US EPA, 2016a)). Emission standards are set forth in a tiered approach, depending on the engine manufacture year. Prior to 1996, off-road engines were not regulated. The first emission standards, known as Tier 1 standards, began to be phased in by power rating in 1996. Tier 2 standards began in 2001, Tier 3 standards in 2006 and Tier 4 standards in 2014. Table C-1 shows the off-road diesel engine emission standards by engine power rating and engine tier (ECCC, 2005/US EPA, 2016a). The off-road diesel engine emission standards (ECCC, 2005) specific to engine power rating and corresponding to Tier 3 equipment are applied as emission factors for NO_X, CO, PM, and VOC. Where emission standards are provided for combined NO_X and HC emissions (NO_X+HC), the pollutant-specific emission standards for NO_X and HC are based on the recommended split in the NONROAD model documentation for Tier 2 and Tier 3 engines (US EPA, 2010a, Table 8). VOC emission factors are calculated based on the NMHC emission factor. NMHC emission factor is calculated by subtracting the methane (CH_4) fraction from the total hydrocarbons (THC) (CH_4 is assumed to be 9.8% of HC emissions). VOC emission factor is calculated by applying a VOC-to-NMHC ratio of 1.233, based on the MOVES2014a/ NONROAD model speciation profiles (US EPA, 2016b, Table 10). All particulate matter emissions are assumed to be smaller than 10 microns (PM_{10}) and 97% of the PM is assumed to be smaller than 2.5 microns ($PM_{2.5}$) (US EPA, 2010a).

The mining equipment ranges in power rating from 24 hp (trailer mounted pressure washer) to 1500 hp (ore haul truck). The emissions estimates for off-road mining equipment owned by Lynn Lake Gold Project (LLGP) used Tier 4 emission factors (highlighted in brown color in Table C-1) as this equipment is confirmed to be Tier 4 and the estimates for equipment that will be rented used Tier 3 emission factors for conservatism as it could be Tier 3 or 4 (highlighted in grey color in Table C-1).

SOURCES:

Canadian Off-Road Compression-Ignition Engine Emission Regulations (ECCC, 2005)

Nonroad Compression-Ignition Engines - Exhaust Emission Standards (US EPA, 2016a)

The US EPA NONROAD model (US EPA, 2005) calculates the SO_2 emission factors based on the sulphur content in diesel fuel and equipment-specific fuel consumption rates. The Sulphur in Diesel Fuel Regulations (ECCC, 2002) set a maximum limit of 15 mg/kg for sulphur contained in off-road diesel fuels in Canada effective 2010. The sulphur content of the diesel fuel can vary but cannot exceed the 15 mg/kg limit; this assessment conservatively uses the maximum limit. The emission factor for SO_2 is converted to g/L using the density of diesel (0.85 kg/L).

The SO_2 emission factor is calculated using the following equation:

$$EF\ (g/L) = Sulphur\ Content\left(\frac{mg}{kg}\right) \times Conversion\ Factor\left(2\,\frac{S}{SO_2}\right) \times Unit\ Conversion\left(\frac{g}{1000mg}\right) \times Diesel\ Density\ (0.85\,\frac{kg}{L})$$

Equation C-1

where

EF - Emission factor (g/L)

Sulphur Content	-	Sulphur content in off-road diesel fuel (mg/kg) assumed equal to the maximum suplhur limit (15 mg/kg) based on the Sulphur in Diesel Regulations (ECCC, 2002).
Conversion Factor (2)	-	Conversion factor equal to the ratio of molecular weights of SO_2 and S: SO_2/S=64/32=2.
Diesel Density	-	Density of diesel fuel (0.85 kg/L).

The fuel consumption for each piece of mining equipment is calculated using the following equation:

$$Fuel\ Consumption\ (L/hr) = Engine\ Power\ (hp) \times BSFC\ \left(\frac{lb\ diesel}{hp\ hr}\right) \times Unit\ Conversion\ \left(\frac{kg}{2.205\ lb}\right) \times \frac{1}{Diesel\ Density\ (0.85\ \frac{kg}{L})}$$

Equation C-2

where

Engine Power	-	Power rating of equipment (hp)
BSFC	-	Brake Specific Fuel Consumption (BSFC) by engine power rating (lb diesel/hp-hr) based on US EPA NONROAD model documentation (US EPA, 2010a, Table A4)
Diesel Density	-	Density of diesel fuel (0.85 kg/L).

Brake specific fuel consumption (BSFC) by engine power rating is obtained from the US EPA NONROAD model documentation (US EPA, 2010a, Table A4). The BSFC provides fuel consumption for each type of equipment in relation to the power rating of the equipment (lb fuel/hp-hr).

C.2.1.2 On-Road Diesel Exhaust Emission Factors

Emissions factors for on-road diesel equipment are derived from the MOVES2014a model for a rural unrestricted road type, including winter and summer seasons. Since MOVES2014a was originally developed for the United States, it does not include Canadian provinces. Therefore, a surrogate US county and state (Hill County, Montana) was selected to represent the Project location in terms of local meteorological conditions. The model was run for a rural unrestricted road type that best represents the provincial, access and haul roads, for winter and summer seasons. The emission factors for each equipment type and substance are listed in Table C-2. The MOVES2014a emission factors are expressed in units of grams per vehicle-miles traveled (g/VMT).

Table C-2 US EPA MOVES 2014 Emission Factors for On-Road Diesel Engines

Equipment Type	Season	Emission Factors (g/VMT)									
		SO_2	NO_X	CO	DTSP	DPM_{10}	$DPM_{2.5}$	FTSP	FPM_{10}	$FPM_{2.5}$	VOC

	Winter	1.38E-02	5.17E+00	1.14E+00	3.02E-01	3.02E-01	1.82E-01	—	—	—	2.23E-01
Combination Long-haul Truck	Summer	1.49E-02	6.02E+00	1.44E+00	3.81E-01	3.81E-01	2.48E-01	—	—	—	2.74E-01
	Winter	1.46E-02	6.47E+00	1.44E+00	3.81E-01	3.81E-01	2.48E-01	—	—	—	2.74E-01

NOTES:
For the MOVES2014a model, winter is assumed 6 months: November to April and summer is assumed 6 months: May to October.

C.2.2 EXPLOSIVE DETONATION EMISSION FACTORS

Explosive detonations during blasting result in emissions. The substantive air contaminants emitted from ammonium nitrate fuel oil emulsion explosives detonation used by the Project are NO_x, CO, and SO_2. US EPA Explosives Detonation emission factors for the substances considered are listed in Table C-3 in units of kilograms per megagram (kg/Mg) (US EPA 1980).

Table C-3 NO_x, CO and SO_2 Emission Factors for Ammonium Nitrate Fuel Oil Emulsion Explosives Detonation

Activity	Emission Factor (kg/Mg) [a]		
	NO_x	CO	SO_2
Explosive Detonation	8	34	1

NOTE:
[a] US EPA AP-42 emission factor rating D
SOURCE:
US EPA AP-42 Table 13.3-1 (1980)

C.2.3 FUGITIVE EMISSION FACTORS

C.2.3.1 Fugitive Dust Emission Factors

Table C-4 contains a summary of the emission factors used in calculating the fugitive dust emissions from project activities (e.g., drilling, blasting, unpaved road dust, etc.). Emission factors are given for total suspended particulate matter (TSP), inhalable particulate matter (PM_{10}), and respirable particulate matter ($PM_{2.5}$) with the applicable particle size multiplier. The table summarizes applied parameters to the individual project activities.

Table C-4 also presents an emission factor rating. Each emission factor is assigned a confidence rating based on the performance of the estimated values to test data representative of the source of air emission. The ratings suggest the likely variability of the calculated values to actual site conditions. The following list represents the emission factor rating from A to E as described by the US EPA AP-42:

- A — Excellent. Factor is developed from A- and B-rated source test data taken from many randomly chosen facilities in the industry population. The source category population is sufficiently specific to minimize variability.
- B — Above average. Factor is developed from A- or B-rated test data from a "reasonable number" of facilities. Although no specific bias is evident, it is not clear if the facilities tested represent a random sample of the industry. As with an A rating, the source category population is sufficiently specific to minimize variability.

- C — Average. Factor is developed from A-, B-, and/or C-rated test data from a reasonable number of facilities. Although no specific bias is evident, it is not clear if the facilities tested represent a random sample of the industry. As with the A rating, the source category population is sufficiently specific to minimize variability.
- D — Below average. Factor is developed from A-, B- and/or C-rated test data from a small number of facilities, and there may be the reason to suspect that these facilities do not represent a random sample of the industry. There also may be evidence of variability within the source population.
- E — Poor. Factor is developed from C- and D-rated test data, and there may be the reason to suspect that the facilities tested do not represent a random sample of the industry. There also may be evidence of variability within the source category population.

Table C-4 Emission Factors for Major Sources of Fugitive Dust Emissions

#	Project Activity	Emission Factor				Particle Size Multiplier (k_1, k_2, k_3, k_4)	Parameters	Emission Factor Rating	Reference

C.2.3.2 Fugitive Hydrogen Cyanide Emission Factors

Table C-5 and Table C-6 contain a summary of the emission factors used in calculating the fugitive hydrogen cyanide emissions from the processing plant (leaching and desorption) and the tailings management facility (TMF). Hydrogen Cyanide emission factors and the parameters such as volatilization rate of cyanide were obtained from the Australian Government Department of the Environment and Heritage (DEH) National Inventory Report Emission estimation technique manual (NPI, 2006)

Table C-5 Emission Factors for Fugitive Hydrogen Cyanide Emissions from the Processing Plant

Activity	HCN Emission Factor [a]
	%
Hydrogen Cyanide from Leaching	1
Hydrogen Cyanide from Desorption	1

NOTE:
[a] % based on NaCN feed rate
SOURCE:
Emission factors are obtained from NPI 2006

Table C-6 Emission Factors for Fugitive Hydrogen Cyanide Emissions from the TMF

Activity	HCN Emission Factor [a, b]
	g/m^3
Hydrogen Cyanide from Tailings Management Facilities	$C_{CN} * V\%/100$

NOTES:
C_{CN} = Cyanide concentration in water entering the TSF, (g CN / m^3)
V% = Volatilization rate of cyanide (%) depending on the pH of the water to the TSF
[a] pH of the water is assumed to be 8.5 based on information from Q'Pit (Q'Pit, 2019)
[b] C_{CN} was based on the design specification
SOURCE:
Emission factor is calculated based on NPI 2006 methodology

C.2.4 POWER GENERATOR EMISSION FACTORS

NO_X, CO, PM and VOC emission factors for the diesel power generator at Gordon were based on the manufacturer's specifications whereas the SO_2 emission factors were calculated based on the sulphur content (15 mg/kg) in diesel fuel and equipment-specific fuel consumption rates as shown in Equation C-1 and Equation C-2. The emission factors for the CACs are listed in Table C-7.

Table C-7 Power Generator Emission Factor

Equipment	Make	Model	Emission Factors (g/hp-hr)						
			SO_2[a]	NO_X	CO	DTSP	DPM_{10}	$DPM_{2.5}$	VOC
Diesel Generator	MTU	6R 1600 DS300	2.54E-02	3.90E+00	5.20E-01	4.00E-02	4.00E-02	3.88E-02	2.71E-01

NOTES:
[a] SO_2 emission factor is in g/L
Both power generators are 300 kW each

C.2.5 TEMPORARY MOBILE CRUSHING PLANT

C.2.5.1 Diesel Exhaust Emission Factor from Mobile Crushing Plant

The temporary mobile crushing plant results in emissions. Exhaust emission emitted from the operation of temporary mobile crusher are SO_2, NO_x, CO, $DPM_{2.5}$, DPM_{10}, DTSP, and VOC. Exhaust emission factors for the temporary mobile crusher are derived using the NONROAD model documentation (US EPA, 2010a) and are shown in Table C-8. The details on how these emission factors are derived are explained in Section C.2.1.1.

Table C-8 Exhaust Emission Factors from Temporary Mobile Crusher

Activity	Manufacturer [a]	Model [a]	Engine Power [a]	Emission Factor [b] (g/hp-hr) \[c]						
			hp	SO_2	NO_X	CO	DTSP	DPM_{10}	$DPM_{2.5}$	VOC
Temporary Mobile Crusher	Patriot	P400	400	0.025	2.800	2.600	0.150	0.150	0.146	0.220

NOTES:
[a] Manufacturer make, model and power rating were assumed based on a similar project.
[b] Emission factor is derived from Canadian Off-Road Compression-Ignition Engine Emission Regulations (ECCC, 2005) and additional information can be found in Section C.2.1.1 of this report.
[c] SO_2 emission factor is in g/L

C.2.5.2 Fugitive Dust Emission Factor from Mobile Crushing Plant

US EPA crushed stone processing and pulverized mineral processing fugitive dust emission factors were used to calculate the fugitive dust emission from the temporary mobile crusher. The US EPA emission factor is summarized in Table C-29.

Table C-9 Fugitive Dust Emission Factors from Temporary Mobile Crusher

Activity	Emission Factor [a] (kg/Mg)		
	FTSP [b]	FPM_{10} [b]	$FPM_{2.5}$ [b, c]
Temporary Mobile Crusher	0.018	0.007	0.007

NOTES:

[a] US EPA AP-42 Table 11.19.2-1 (2004)

[b] Uncontrolled emission factor from tertiary crushing, screening, and conveyor transfer point at loading and unloading are accounted

[c] $FPM_{2.5}$ emission factor for uncontrolled equipment is not available hence conservatively assumed FPM_{10} = $FPM_{2.5}$

C.3 OPERATION EMISSIONS INVENTORY

C.3.1 WORST-CASE YEAR AND EMISSION SOURCES

The operation phase has been evaluated by quantifying emissions for a “worst-case” year of operation at both Gordon and MacLellan. The worst-case years of operation coincide with the peak production rate that will result in the highest emissions. The worst-case year for the operation was selected based on the highest production rate, the largest number of mining equipment units and the highest movements of overburden, mine rock and ore measured in tonnes. Year 7 the worst-case year of operation for the MacLellan site and Year 2 was determined to be the worst-case year of operation for the Gordon site. The following air emissions were estimated for the worst-case operation year:

- Diesel combustion exhaust emissions from mining off-road equipment and haul trucks
- Diesel combustion exhaust emissions from on-highway trucks and on-road vehicles
- Diesel combustion emissions from a permanent diesel generator
- Fugitive dust and explosives detonation emissions from drilling and blasting
- Mechanically generated dust by mining off-road equipment movement
- Fugitive dust emissions from bulldozing and grading
- Fugitive dust emissions from truck loading and unloading
- Mechanically generated dust by truck traffic along haul roads and the access road
- Mechanically generated dust by truck traffic along PR 391
- Fugitive dust emissions from wind erosion of stockpiles.

- PM emissions from the primary and secondary crushers
- PM emissions from dust collectors at the ore milling and processing plant gold room
- Fugitive dust emissions from wind erosion of the TMF dry banks
- Fugitive HCN emissions from the processing plant leach and adsorption tanks
- Fugitive HCN emissions from the TMF pond.

The emissions from the worst-case year of operation at MacLellan site Year 7 and Gordon site Year 2 were estimated and are discussed in this report.

C.3.2 GENERAL ASSUMPTIONS

The following general and operational assumptions were used to estimate Project operation emissions due to combustion sources:

- Purchased mining equipment at MacLellan and Gordon comply with Tier 4 emission standards.
- Rental mining equipment at MacLellan and Gordon are assumed to comply with Tier 3 emission standards.
- Power ratings (hp) for off-road and on-road equipment are based on manufacturer's specifications using typical mining equipment manufacturers and models.
- Utilization (load) factors for off-road construction equipment from the US EPA NONROAD model (US EPA, 2010).
- Assumed no pit retention (refer to Section C.1.3.3 for additional information) for diesel exhaust PM based on professional judgement and to be conservative .

The following general and operational assumptions were used to estimate Project operation fugitive dust emissions:

- Seventy-five percent dust control efficiency on haul roads during the summer, corresponding to the expected control efficiency achievable from the application of water twice daily (US EPA, 2006a). Summer is assumed to be May to October.
- Ninety percent natural mitigation efficiency on haul roads during winter (Golder Associates, 2012). Winter is assumed to be November to April.
- Eleven percent dust natural mitigation efficiency on paved roads during summer (calculated based on the equation from US EPA 2011 and the measured precipitation data).
- Ninety-seven percent dust natural mitigation efficiency on paved roads during winter (calculated based on the equation from US EPA 2011 and the measured precipitation data).

- Fugitive dust control not applied during bulldozing and grading, off-road equipment in transition, truck loading and unloading, and material transfer to and from the temporary topsoil and overburden stockpiles.
- Fugitive dust emissions from water trucks is assumed to be zero because of the wet road surface due to water application based on professional judgement .

C.3.3 EMISSION RATES

C.3.3.1 CAC Emissions from Diesel Engines

C.3.3.1.1 Off-Road Diesel Exhaust Emissions

The off-road equipment which will be used at MacLellan and Gordon sites during Year 7 and Year 2 are presented in Table C-10 and the equipment is divided into five categories as follows:

- Open Pit Mining
- Overburden Removal
- Drilling & Blasting
- Stockpile Rehandling
- Maintenance and Other Supporting Equipment

Table C-1 summarizes the parameters used to calculate the off-road diesel exhaust emissions at MacLellan and Gordon. Table C-11 summarizes the hourly and daily CAC emission rates during Year -7 and Year 2 at MacLellan and Gordon, respectively. Emission rate totals are given per equipment type. The rates were determined using Equation C-3 (NO_x, CO, TSP, PM_{10}, $PM_{2.5}$, VOC) and Equation C-4 (SO_2), the emission factors listed in Table C-1, and the equipment parameters in Table C-10.

Emissions of NO_X, CO, PM and VOC for each off-road equipment type are determined as follows:

$$ER_h\ (g/s) = Number\ of\ Units \times Engine\ Power\ (hp) \times Emission\ Factor\ \left(\frac{g}{hp\ hr}\right) \times Engine\ Load\ Factor\ (\%) \times Unit\ Conversion\ \left(\frac{hr}{3600\ s}\right)$$

Equation C-3

where

ER_h	-	Hourly emission rate (g/s)
Number of Units	-	Number of Equipment
Engine Power	-	Power rating of equipment (hp)

Emission Factor	-	Canadian off-road compression-ignition engine emission standards (g/hp-hour) based on Tier 3 engines (ECCC, 2005)
Load Factor	-	Equipment load factor (%) by equipment type based on US EPA NONROAD model documentation (US EPA, 2010b). Defined as the fraction of actual engine output relative to maximum rated power, taking into account that engines are operating somewhere between idle speed and full power.

The engine power rating associated with each piece of equipment is sourced from the manufacturer's information.

The engine load factor (LF) is a measure of the fraction of actual engine output relative to maximum rated power. Equipment engine load factors from the NONROAD model documentation (US EPA, 2010b) are used to calculate project emissions. An 80% LF is used for haul trucks, which is truck utilization, accounting for time for loading/unloading and breaks for operators.

Emissions of SO_2 for each off-road equipment type are determined using the following equation, assuming that all diesel sulphur is oxidized:

$$ER_h\,(g/s) = Number\ of\ Units \times Fuel\ Consumption\left(\frac{L\ diesel}{hr}\right) \times Emission\ Factor\left(\frac{g}{L}\right) \times Unit\ Conversion\left(\frac{hr}{3600\,s}\right)$$

Equation C-4

where

ER_h	-	Hourly emission rate (g/s)
Number of Units	-	Number of Equipment
Fuel Consumption	-	Fuel consumption of equipment (L/hr)
Emission Factor	-	SO_2 emission factor per litre of fuel consumption (g/L).

C.3.3.1.2 On-Road Diesel Exhaust Emissions

On-road diesel exhaust emissions were estimated using the MOVES emission factors (g/VMT) and the number of vehicle round trips per hour (and day) and the length of the road. Table C-12 summarizes the parameters used to calculate the on-road diesel exhaust emissions and Table C-13 summarizes the hourly and daily CAC emission rates. Emission rate totals are given per equipment type.

The emission rates were determined using Equation C-5, the emission factors listed in Table C-2, and the equipment parameters in Table C-12.

On-road equipment emission rates are determined using the following equation:

$$ER_h\ (g/s) = Road\ Length\ (km) \times Round\ Trip\ Factor(2) \times Number\ of\ Trips \left(\frac{trips}{hr}\right) \times Emission\ Factor\ \left(\frac{g}{VMT}\right) \times Unit\ Conversion\ \left(0.621\frac{m}{km}\right) \times Unit\ Conversion\ \left(\frac{hr}{3600\ s}\right)$$

Equation C-5

where

ER_h	-	Hourly emission rate (g/s)
Road Length	-	Haul road length (km)
Number of Trips	-	Number of trips per truck per hour (trips/hr)
Round Trip Factor (2)	-	A factor of 2 accounting for a round trip distance
Emission Factor	-	Substance-specific emission factor based on MOVES2014 (g/VMT).

Table C-10 Off-Road Equipment Parameters for CAC Emission Rate

NOTES:

[a] Hourly and daily emission rates are for the number of equipment presented in Table C-10

[b] SO_2 hourly emission rates were calculated using Equation C-4 (as shown in Section C.1.3.1.1) and other substances emission rates were calculated using Equation C-3 (as shown in Section C.1.3.1.1)

[c] Daily emission rates were calculated using the hourly emission rate and equipments operating hours per day

Table C-12 On-Road Equipment Parameters for CAC Emission Rate

Activity	Truck Description	MOVES Vehicle Type	Road Length	Number of Round Trips

NOTES:

[a] Hourly and daily emission rates were calculated using the parameters presented in Table C-12

[b] Hourly emission rates were calculated using Equation C-5 (as shown in Section C.1.3.1.2) for all substances

[c] Daily emission rates were calculated using Equation C-5 (as shown in Section C.1.3.1.2) but uses the trips per day instead of tips per hour and respective unit conversion

C.3.3.2 Explosive Detonation Emissions

Ammonium nitrate fuel oil emulsion explosives will be used for the blasting. Table C-14 summarizes the hourly and daily CAC detonation emission rates for Year 7 and Year 2 at MacLellan and Gordon, respectively. The emission rates were determined using Equation C-6 (SO_2, NO_x and CO) and detonation emission factors in Table C-3. Based on the information provided by LLGP, blasting will occur every third day and the duration of blasting will be approximately one hour.

Emissions of SO_2, NO_X and CO from the explosives detonation are determined from:

$$\begin{aligned} ER_h\ (g/s) &= Number\ of\ holes\ per\ blast \left(\frac{holes}{blast}\right) \times Blast\ per\ hour \left(\frac{blast}{hr}\right) \\ &\times Explosive\ Usage \left(\frac{kg\ of\ explosives}{hole}\right) \times Unit\ Conversion \left(\frac{tonnes}{1000\ kg}\right) \\ &\times Emission\ Factor \left(\frac{kg}{tonnes\ of\ explosives}\right) \times Unit\ Conversion \left(\frac{1000\ g}{kg}\right) \\ &\times Unit\ Conversion \left(\frac{hr}{3600\ s}\right) \end{aligned}$$

Equation C-6

where

ER_h	-	Hourly emission rate (g/s)
Explosive Usage	-	Amount of explosives used per hole (kg/hole)
Emission Factor	-	US EPA emission factors for Explosives Detonation (kg/tonnes of explosives) (US EPA 1980)

Table C-14 Explosive Detonation Emission Rates

Activity Description	Hourly CAC Emission Rates (g/s) [a]			Daily CAC Emission Rates (g/s) [b, c]		
	SO_2	NO_X	CO	SO_2	NO_X	CO
MacLellan Site (Year 7)						
Open Pit						
Explosives Detonation	1.23E+01	9.84E+01	4.18E+02	1.23E+01	9.84E+01	4.18E+02
Gordon Site (Year 2)						
Open Pit						
Explosives Detonation	8.89E+00	7.11E+01	3.02E+02	8.89E+00	7.11E+01	3.02E+02

NOTES:

[a] Hourly emission rates were calculated using the Equation C-6 (as shown in Section 1.3.2)

[b] Daily emission rates were calculated using the Equation C-6 (as shown in Section 1.3.2) but use number of blasts per day and the respective conversion factor

[c] Blasting occurs every third day between 7 pm and 8 pm

C.3.3.3 Fugitive Emissions

C.3.3.3.1 Fugitive Dust Emission

There are various mining activities that create fugitive dust including TSP, PM_{10} and $PM_{2.5}$ emissions. The mining activities are summarized into the following categories:

- Drilling
- Blasting
- Truck loading
- Truck unloading
- Unpaved road dust
- Paved road dust
- Bulldozing
- Grading
- Wind erosion
- Primary Crusher
- Secondary Crusher
- Drying Oven
- Induction Furnace

Daily and annual emission rates from all of the above activities were calculated using the emission rates listed in Table C-4. The fugitive TSP, PM_{10} and $PM_{2.5}$ emission rates from the above activities are calculated using the Equation C-7 and Equation C-10 to Equation C-18. The source-specific parameters and fugitive TSP, PM_{10} and $PM_{2.5}$ emission rates for MacLellan, Gordon and Provincial Road sources are summarized in Table C-15, Table C-16 and Table C-17, respectively.

Fugitive TSP, PM_{10} and $PM_{2.5}$ emission rates for each activity were determined using the below equations:

Drilling:

$$ER_h\ (g/s) = Number\ of\ Holes\ Drilled\left(\frac{hole}{hr}\right) \times (1 - Pit\ Retention\%) \times\ Emission\ Factor\ \left(\frac{kg}{hole}\right) \times Unit\ Conversion\ \left(\frac{1000\ g}{kg}\right) \times Unit\ Conversion\ \left(\frac{hr}{3600\ s}\right)$$

Equation C-7

Where:

ER_h	-	Hourly emission rate (g/s)
Pit Retention %	-	Percentage of emissions retained in the pit
Emission Factor	-	Particle size-specific emission factor (kg/hole).

The percentage of PM emissions that are retained in the open pit depends on the depth of the pit and the particle size (Winges 1986). A 50% pit retention for TSP emissions and 5% pit retention for PM_{10} emissions was applied based on the recommendations in the Australian Emission Manual for Mining (NPI 2012). The fraction of $PM_{2.5}$ emissions retained in the open pits were estimated based on the original Winges equation as shown in Equation C-8 and Equation C-9 (Winges 1981) assuming a pit depth of 245 m for MacLellan site (Year 7) and 150 m for Gordon site (Year 2). The calculated pit retention fraction of $PM_{2.5}$ emissions is 2% for the open pit at the MacLellan site and 1% for the open pit at the Gordon site.

$$Es = \frac{1}{\left(1 + \left(\frac{U_d\left(\frac{m}{s}\right)}{K\left(\frac{m^2}{s}\right)}\right) \times H\ (m)\right)} \times 100$$

Equation C-8

Where:

E_s	-	Percentage of emission escaped from the pit
U_d	-	Deposition velocity (m/s)
K	-	Eddy diffusivity (m^2/s)
H	-	Depth of the pit (m)

$$Er = 1 - Es$$

Equation C-9

Where:

E_r	-	Percentage of emission retained in the pit or Pit Retention %

Blasting:

$$ER_h\ (g/s) = Number\ of\ Blast\left(\frac{blast}{hr}\right) \times (1 - Pit\ Retention\%) \times\ Emission\ Factor\ \left(\frac{kg}{blast}\right) \times Unit\ Conversion\ \left(\frac{1000\ g}{kg}\right) \times Unit\ Conversion\ \left(\frac{hr}{3600\ s}\right)$$

Equation C-10

Where:

ER_h	-	Hourly emission rate (g/s)
Pit Retention %	-	Percentage of emissions retained in the pit
Emission Factor	-	Particle size-specific emission factor (kg/blast).

Bulldozing and Grading:

$$ER_h\ (g/s) = Number\ of\ Units \times Utilization\ Factor\ (\%) \times (1 - Pit\ Retention\%) \times Emission\ Factor\ \left(\frac{lb}{hr}\right) \times Unit\ Conversion\ \left(\frac{kg}{2.205\ lb}\right) \times Unit\ Conversion\ \left(\frac{1000\ g}{kg}\right) \times Unit\ Conversion\ \left(\frac{hr}{3600\ s}\right)$$

Equation C-11

where

ER_h	-	Hourly emission rate (g/s)
Number of Units	-	Number of Equipment
Utilization Factor (UF)	-	Utilization factor defined as the ratio of net operating time versus gross operating time. The utilization factor accounts for the intermittent bulldozing during the operating hours. The utilization factor is assumed to equal to the equipment load factor (LF) which is based on US EPA NONROAD model documentation (US EPA, 2010b).
Pit Retention %	-	Percentage of emissions retained in the pit
Emission Factor	-	Particle size-specific emission factor for bulldozing of overburden (lb/hr).

Material Loading and Unloading:

$$ER_h\ (g/s) = Material\ \left(\frac{tonne}{hr}\right) \times (1 - Pit\ Retention\%) \times Emission\ Factor\ \left(\frac{kg}{tonne}\right) \times Unit\ Conversion\ \left(\frac{1000\ g}{kg}\right) \times Unit\ Conversion\ \left(\frac{hr}{3{,}600\ s}\right)$$

Equation C-12

where:

ER_h	-	Hourly emission rate (g/s)
Material	-	Loaded/unloaded material (tonne/hr)
Pit Retention %	-	Percentage of emissions retained in the pit
Emission Factor	-	Particle size-specific emission factor

Off-Road Equipment Transition:

$$ER_h\ (g/s) = Number\ of\ Units \times Utilization\ Factor\ (\%) \times Average\ Speed\ \left(\frac{km}{hr}\right) \times (1 - Pit\ Retention\ (\%)) \times Emission\ Factor\ \left(\frac{lb}{VMT}\right) \times Unit\ Conversion\ \left(281.9 \frac{g/VKT}{lb/VMT}\right) \times \left(\frac{hr}{3{,}600\ s}\right)$$

Equation C-13

Where:

ER_h	-	Hourly emission rate (g/s)
Number of Units	-	Number of Equipment
Utilization Factor (UF)	-	Utilization factor defined as the ratio of net operating time versus gross operating time. The utilization factor accounts for the intermittent bulldozing during the

		operating hours. The utilization factor is assumed equal to the equipment load factor (LF) which is based on US EPA NONROAD model documentation (US EPA, 2010b).
Average Speed	-	Average speed of the equipment (km/hr)
Pit Retention %	-	Percentage of emissions retained in the pit
Emission Factor	-	Particle size-specific emission factor (lb/VMT).

Unpaved Road Dust:

$$ER_h\ (g/s) = Road\ Length\ (km) \times Round\ Trip\ Factor(2) \times Number\ of\ Trips \left(\frac{trips}{hr}\right) \times (1 - Pit\ Retention\ (\%)) \times Emission\ Factor\ \left(\frac{lb}{VMT}\right) \times (1 - Control\ Efficiency\ (\%)) \times Unit\ Conversion\ \left(281.9 \frac{g/VKT}{lb/VMT}\right) \times Unit\ Conversion\ \left(\frac{hr}{3{,}600\ s}\right)$$

Equation C-14

Where:

ER_h	-	Hourly emission rate (g/s)
Road Length	-	Haul road length (km)
Round Trip Factor (2)	-	A factor of 2 accounting for a round trip distance
Number of Trips	-	Number of trips per truck per hour (trips/hr)
Pit Retention %	-	Percentage of emissions retained in the pit
Emission Factor	-	Particle size-specific emission factor (lb/VMT).
Control Efficiency	-	Control efficiency (%). Assumed 75% control efficiency in summer corresponding to watering twice daily (US EPA, 2006a) and 90% natural mitigation efficiency in winter (Golder Associates, 2012).

Paved Road Dust:

$$ER_h\ (g/s) = Road\ Length\ (km) \times Round\ Trip\ Factor(2) \times Number\ of\ Trips \left(\frac{trips}{hr}\right) \times Emission\ Factor\ \left(\frac{lb}{VMT}\right) \times Unit\ Conversion\ \left(281.9 \frac{g/VKT}{lb/VMT}\right) \times Unit\ Conversion \left(\frac{hr}{3{,}600\ s}\right) \times (1 - Natural\ Mitigation\ Efficiency\ (\%))$$

Equation C-15

Where:

ER_h	-	Hourly emission rate (g/s)
Road Length	-	Haul road length (km)
Round Trip Factor (2)	-	A factor of 2 accounting for a round trip distance
Number of Trips	-	Number of trips per truck per hour (trips/hr)
Emission Factor	-	Particle size-specific emission factor (lb/VMT).

Natural Mitigation Efficiency	-	97% natural mitigation efficiency in winter and 11% in summer were calculated based on the equation from US EPA AP-42 (US EPA 2011) and the number of days with measurable precipitation.

Wind Erosion:

$$ER_h\ (g/s) = Disturbed\ Area\ (m^2) \times Number\ of\ Disturbances\ per\ hour\ \left(\frac{disturbance}{hr}\right) \times Emission\ Factor\ \left(\frac{g}{m^2}\right) \times Unit\ Conversion \left(\frac{hr}{3{,}600\ s}\right)$$

Equation C-16

where:

ER_h	-	Hourly emission rate (g/s)
Disturbed Area	-	Assumed disturbed area (100 m^2) of the stockpile.
Number of Disturbances	-	Number of disturbances per hour equal to the number of truck loadings per hour.
Emission Factor	-	Particle size-specific emission factor for wind erosion (g/m^2/disturbance)

Primary Crusher, Secondary Crusher, and Induction Furnace Dust Collector:

$$ER_h\ (g/s) = Volumetric\ Flow\ Rate \left(\frac{m^3}{hr}\right) \times Inlet\ Dust\ Concentration \left(\frac{g}{m^3}\right) \times\ (1 - Control\ Efficiency\%) \times Unit\ Conversion\ \left(\frac{hr}{3600\ s}\right)$$

Equation C-17

where:

ER_h	-	Hourly emission rate (g/s)
Volumetric Flow Rate	-	Amount of dust sent to dust collector based on the design specification
Inlet Dust Concentration	-	Amount of size-specific particles present in one cubic metre (g/m^3) based on the design specification
Control Efficiency	-	Assumed 98% of control efficiency for dust collectors based on the design specification

Drying Oven:

$$ER_h\ (g/s) = Number\ of\ Batches\ \left(\frac{\#}{day}\right) \times Metal\ Sludge\ Feed\ Rate \left(\frac{kg}{batch}\right) \times\ Unit\ Conversion\ \left(\frac{tonne}{1000\ kg}\right) \times Emission\ Factor\ \left(\frac{kg}{tonne}\right) /\ operating\ hours \left(\frac{hr}{day}\right) \times\ Unit\ Conversion\ \left(\frac{1000\ g}{kg}\right) \times\ Unit\ Conversion\ \left(\frac{hr}{3600\ s}\right)$$

Equation C-18

where:

ER_h	-	Hourly emission rate (g/s)
Number of Batches	-	Number of batches per day
Metal Sludge Feed Rate	-	Material processed per each batch
Operating hours	-	Equipment operating hours per day (hr/day)

NOTES:
[a] Parameters used for emission calculation are obtained from the Q'Pit mine plan or provided by Ausenco or estimated using the data by Q'Pit or Ausenco
Hourly emission rates were calculated using the Equation C-15 (as shown in Section 1.3.3.1)
Daily emission rates were calculated using the Equation C-15 (as shown in Section 1.3.3.1) but uses trips per day instead of trips per hour and the respective unit conversion

C.3.3.3.2 Fugitive Hydrogen Cyanide Emissions

Table C-18 summarizes the parameters used for hourly and daily hydrogen cyanide (HCN) emission rates from the processing plant and TMF. The emission rates from leaching and desorption were determined using Equation C-19, the emission factors listed in Table C-5, and the parameters in Table C-18. The emission rates from the TMF were determined using Equation C-20, the emission factors listed in Table C-6, and the parameters in Table C-18. As per Australian NPI manual (NPI 2006), the sodium cyanide which is used during leaching bonds with the gold to form Au $(CN)_2^-$ complex. During this process, the cyanide is carried through the system in a dissolved form to TSF and are released as gaseous hydrogen cyanide.

Leaching and Desorption HCN emissions are determined from:

$$ER_h\ (g/s) = Feed\ Rate\ \left(\frac{kg}{hr}\right) \times Emission\ Factor\ (\%)\ \times Unit\ Conversion\ \left(\frac{1000\ g}{kg}\right) \times Unit\ Conversion\ \left(\frac{hr}{3600\ s}\right)$$

Equation C-19

where

ER_h	-	Hourly emission rate (g/s)
Feed Rate	-	Sodium Cyanide Feed Rate based on the design specification
Emission Factor	-	1% of the total cyanide added to the circuit is lost through HCN volatilization across all tanks (NPI 2006)

TMF HCN emissions are determined from:

$$ER_h\ (g/s) = Water\ Discharge\ Rate\ \left(\frac{m^3}{hr}\right) \times Emission\ Factor\ \left(\frac{g}{m^3}\right) \times Unit\ Conversion\ \left(\frac{hr}{3600\ s}\right)$$

Equation C-20

where

ER_h	-	Hourly emission rate (g/s)
Feed Rate	-	Sodium Cyanide Feed Rate based on the design specification
Emission Factor	-	Emission factor for HCN emission from TMF (g/m^3) based on the design specification

Table C-18 Parameters and Emission Rate for Fugitive Hydrogen Cyanide

Activity Description	NaCN Feed Rate	Water Discharge Rate to TMF	NaCN Content in Discharge Water	NaCN Volatilization	Hourly HCN Emission Rates (g/s)	Daily HCN Emission Rates (g/s)
	kg/h	m³/h	mg/L	%	g/s	g/s
MacLellan Site (Year 7)						
Processing Plant						
Hydrogen Cyanide from Leaching	112	—	—	—	3.10E-01	3.10E-01
Hydrogen Cyanide from Desorption	1.63	—	—	—	4.53E-03	4.53E-03
Hydrogen Cyanide from TMF	—	374.4	10.0	70%	7.28E-01	7.28E-01
NOTE: Hourly and Daily emission rates are the same as it is a continuous operation						

C.3.3.4 CAC Emissions from Power Generator

The emission rates for the diesel power generator (genset) were determined using Equation C-3 (NO_x, CO, TSP, PM_{10}, $PM_{2.5}$, VOC) and Equation C-4 (SO_2). Table C-7 summarizes the emission factors used to calculate the diesel genset emissions and Table C-19 summarizes the hourly and daily emission rates.

Table C-19 Parameters and Emission Rate for Power Generator

Equipment	Engine Power, kW	Hourly and Daily Emission Rate, g/s						
		SO_2	NO_x	CO	DTSP	DPM_{10}	$DPM_{2.5}$	VOC
Diesel Generator	300	4.91E-04	3.70E-01	4.94E-02	3.80E-03	3.80E-03	3.69E-03	2.57E-02
NOTE: Hourly and Daily emission rates are the same as it is a continuous operation								

C.3.4 EMISSION RATE SUMMARY

Table C-20, Table C-21, and Table C-22 summarize the hourly emission rates for the Project,

MacLellan and Gordon, respectively. Similarly, Table C-23, Table C-24 and Table C-25 summarize the daily emission rates for the Project, MacLellan and Gordon, respectively.

Figure C-3 to Figure C-11 shows the Project, MacLellan and Gordon site hourly and daily emission rates for SO_2, NO_x, CO, DTSP, DPM_{10}, $DPM_{2.5}$, FTSP, FPM_{10}, $FPM_{2.5}$, VOC and HCN. These figures also show the emission contributions from applicable source categories for each species.

C.4 CONSTRUCTION EMISSIONS INVENTORY

C.4.1 WORST-CASE YEAR AND EMISSION SOURCES

There are two years in the Project construction phase (defined as Year -2 and Year -1 in reference to the overall Project timeline). Project construction starts in year -2 with works such as road construction, mine platforms, processing plant construction, TMF construction, and preproduction. The worst-case year of construction was selected based on the most overlapping construction activities, the largest number of construction equipment units and the highest construction material movement. The 12-month period from Q2 Year -2 to Q1 Year -1 was determined as the worst-case year of construction for both the Gordon and MacLellan sites.

The annual construction emissions are estimated for SO_2, NO_x, CO, $DPM_{2.5}$, DPM_{10}, DTSP, $FPM_{2.5}$, FPM_{10}, FTSP and VOC and are then compared to the annual operation emissions. The following air emissions were estimated for the worst-case construction year:

- Diesel combustion exhaust emissions from construction off-road equipment and haul trucks
- Diesel combustion exhaust emissions from on-highway trucks and on-road vehicles
- Fugitive dust and explosives detonation emissions from drilling and blasting
- Diesel combustion exhaust emission and fugitive dust from mobile crushing plant
- Mechanically generated dust by construction off-road equipment movement
- Fugitive dust emissions from bulldozing and grading
- Fugitive dust emissions from truck loading and unloading
- Mechanically generated dust by truck traffic along haul roads and the access road
- Fugitive dust emissions from wind erosion of stockpiles.
- The estimated air emissions from the worst-case year from the above-identified activities are discussed below.

C.4.2 GENERAL ASSUMPTIONS

The following general assumptions were used to estimate Project construction emissions due to combustion sources:

- Mine preproduction equipment at MacLellan and Gordon site comply with Tier 4 emission standards.
- Equipment used for road construction, mine platforms, processing plant construction and TMF construction at MacLellan site assumed to comply with Tier 3 emission standards.
- Equipment used for road construction and mine platforms at Gordon site assumed to comply with Tier 3 emission standards (as per Ausenco).
- Power ratings (hp) for off-road and on-road equipment are based on manufacturer's specifications using assumed manufacturers and models.
- Utilization (load) factors for off-road construction equipment from the US EPA NONROAD model (US EPA, 2010b).
- Assumed no pit retention for diesel exhaust PM.
- Assumed 10 hours per shift and 1 shift per day for the activities associated with road construction, mine platforms, processing plant construction, and TMF construction (as per Ausenco).
- Assumed Gordon construction equipment equal to 20% of MacLellan processing plant construction equipment based on professional judgement.
- Assumed 43% load factor for the mobile crusher based on similar equipment load factor from US EPA NONROAD model (US EPA, 2010b).

The following general and operational assumptions were used to estimate Project construction fugitive dust emissions:

- Seventy-five percent dust control efficiency on haul roads during the summer, corresponding to the expected control efficiency achievable from the application of water twice daily (US EPA, 2006a). Summer is assumed to be May to October.
- Ninety percent natural mitigation efficiency on haul roads during winter (Golder Associates, 2012). Winter is assumed to be November to April.
- Eleven percent dust natural mitigation efficiency on paved roads during summer (calculated based on the equation from US EPA 2011 and the measured precipitation data).
- Ninety-seven percent dust natural mitigation efficiency on paved roads during winter (calculated based on the equation from US EPA 2011 and the measured precipitation data).
- Fugitive dust control not applied during bulldozing and grading, off-road equipment in transition, truck loading and unloading, and material transfer to and from the temporary topsoil and overburden stockpiles.

- Fugitive dust emissions from water trucks are assumed to be zero because of the wet road surface due to water application based on professional judgement .
- Assumed no pit retention for fugitive dust PM based on professional judgement and to be conservative.
- Assumed Gordon construction equipment equal to 20% of MacLellan processing plant construction equipment based on professional judgement.

C.4.3 EMISSION RATES

The list of off-road equipment, on-road equipment and their operating hours which are used for road construction, mine platforms, processing plant construction and TMF construction were provided by Ausenco. Tier 3 emission factors were used for these equipment conservatively as it is possible, they could be Tier 3 or 4. The list of off-road equipment, on-road equipment and their operating hours for the mine preproduction were provided by Q'Pit (Q'Pit 2019) and for these equipment Tier 4 emission factor was used.

The methodology used to calculate the construction phase air emissions from diesel exhaust, explosive detonation and fugitive dust are the same as what was used for operation emission. The methodologies associated with diesel exhaust, explosive detonation and fugitive dust are discussed in Section C.3.3.1, Section C.3.3.2 and Section C.3.3.3, respectively. The list of equipment and the parameters which are used for calculating the off-road and on-road equipment worst-case year construction emission are shown in Table C-26 and Table C-27

The methodology used to calculate the diesel exhaust and fugitive dust emission from the temporary mobile crushing plant is discussed below.

C.4.3.1 Diesel Exhaust Emission from Mobile Crushing Plant

The emission rates for the temporary mobile crusher were determined using Equation C-3 (NO_x, CO, TSP, PM_{10}, $PM_{2.5}$, VOC) and Equation C-4 (SO_2).

C.4.3.2 Fugitive Dust Emission from Mobile Crushing Plant

The fugitive dust emission rates for the temporary mobile crusher were determined using Equation C-21.

$$ER_h\ (g/s) = Feed\ Rate\left(\frac{tonnes}{hr}\right) \times Emission\ Factor\left(\frac{kg}{Mg\ or\ tonnes}\right) \times Unit\ Conversion\ \left(\frac{hr}{3600\ s}\right)$$

Equation C-21

where:

ER_h	-	Hourly emission rate (g/s)
Feed Rate	-	Amount of aggregate to the mobile crusher is based on the design specification
Emission Factor	-	US EPA AP-42 Table 11.19.2-1 Particle size-specific emission factor (kg/Mg of aggregate).

C.5 COMPARISON OF CONSTRUCTION AND OPERATION EMISSION INVENTORY

The maximum annual construction and operation emission from the Project, MacLellan and Gordon site are summarized in Table C-31. The findings are summarized below:

Project Emissions:

- Emissions of gaseous CACs (NO_X, CO, SO_2, and VOC) during construction are 50% to 72% less than the corresponding annual emission totals during operation. The highest difference (72%) corresponds to NO_X emissions.
- Emissions of DPM are approximately 25% lesser than the corresponding annual emissions totals during operation. The highest difference (24%) corresponds to TSP and PM_{10} emissions.
- Fugitive particulate matter emissions (TSP, PM_{10}, and $PM_{2.5}$) during construction are 39% to 53% less than the corresponding annual emission totals during operation. The highest difference (53%) corresponds to PM_{10} emissions.

MacLellan Emissions:

- Emissions of gaseous CACs (NO_X, CO, SO_2, and VOC) during construction are 39% to 65% less than the corresponding annual emission totals during operation. The highest difference (65%) corresponds to NO_X emissions.
- Emissions of DPM are approximately 20% higher than the corresponding annual emissions totals during operation. DPM emission during construction is higher because of the use of Tier 3 emission factor for off-road equipment.
- Fugitive particulate matter emissions (TSP, PM_{10}, and $PM_{2.5}$) during construction are 20% to 41% less than the corresponding annual emission totals during operation. The highest difference (41%) corresponds to PM_{10} emissions.

Gordon Emissions:

- Emissions of gaseous CACs (NO_X, CO, SO_2, and VOC) during construction are 65% to 85% less than the corresponding annual emission totals during operation. The highest difference (85%) corresponds to NO_X emissions.
- Emissions of DPM are approximately 77% less than the corresponding annual emissions totals during operation. The highest difference (77%) corresponds to TSP and PM_{10} emissions.
- Fugitive particulate matter emissions (TSP, PM_{10}, and $PM_{2.5}$) during construction are 70% to 76% less than the corresponding annual emission totals during operation. The highest difference (76%) corresponds to PM_{10} and $PM_{2.5}$ emissions.

Table C-31 Comparison of Worst-Case Year Annual Construction and Operation Emission

Appendix D METEOROLOGY/CALMET

D.1 INTRODUCTION

This appendix provides an overview of the meteorological information used for the dispersion modelling completed as part of the Lynn Lake Mine Project (the Project) assessment. Also provided are the technical details and options that were used to apply the CALMET model for the assessment.

Meteorology determines the transport and dispersion of industrial emissions, and hence plays an important role in determining air quality downwind of emission sources. For the air quality assessment, meteorological data for the five-year period from 2012 to 2016 were used to define transport and dispersion parameters. The selection of a five-year period is consistent with the Manitoba Conservation (MC) Guidelines for Air Dispersion Modeling in Manitoba (MC 2006), that requires data for a five-year period when using meteorological data for dispersion modeling. However, Manitoba Conservation (MC) Guidelines for Air Dispersion Modeling in Manitoba don't provide guidelines for model (e.g. CALMET) setup, therefore, Alberta Environment and Parks (AEP) Air Quality Model Guideline (AEP 2013) has been used as guidelines for CALMET options and set up.

Meteorological characteristics vary with time (e.g., season and time of day) and location (e.g., height above ground, terrain features, and land cover properties). Historically, meteorological data measured at one location have been used and extrapolated to reflect conditions across the model domain. For large model domains, this approach fails to recognize that meteorological conditions for any given hour can vary significantly across the domain due to terrain and geophysical differences. Curvilinear airflow can also result from mesoscale and synoptic-scale weather patterns.

Meteorological models are used to provide spatially and temporally varying wind and temperature fields across a model domain to overcome some of the limitations associated with the use of single station measurements. The CALMET meteorological pre-processing program is used to provide temporally and spatially varying meteorological parameters required by the CALPUFF model.

The CALMET pre-processor is available from the website of the model developer (i.e., Exponent Inc. - http://www.src.com/calpuff/calpuff1.htm). At the time of this assessment, the most recent Exponent version of CALMET was Version 6.5.0 level 150223, released June 22, 2015. The corresponding current U.S. EPA version of CALMET is Version 5.8.5, level 151214. Consistent with the AEP Air Quality Model Guideline, Version 6.5.0 was adopted.

D.2 MODEL DOMAIN

D.2.1 Boundaries

The model domain adopted for this assessment extends from 50.8806 degrees latitude to 51.2275 degrees latitude (resulting in a north south extent of 48 km), and from 114.7326 degrees longitude to 114.1426 degrees longitude (resulting in an east west extent of 70 km), as shown in Map D-1. The study domain covers a 3,360 km^2 area, the extents of which are provided in Table D-1. A horizontal grid spacing of 500 m was selected for the CALMET simulation. The study area therefore corresponds to 140 rows by 96 columns. With this grid spacing, it was possible to maximize run time and file size efficiencies while still capturing terrain feature influences on wind flow patterns.

To simulate transport and dispersion processes, it is important to simulate the representative vertical profiles of wind direction, wind speed, temperature, and turbulence intensity within the atmospheric boundary layer (i.e., the layer within about 2,000 m above the Earth's surface). To capture this vertical structure, twelve vertical layers were selected. CALMET defines a vertical layer as the midpoint between two faces (i.e., thirteen faces correspond to twelve layers, with the lowest layer always being ground level or 10 m). The vertical faces used in this study are 0 m, 20 m, 40 m, 80 m, 120 m, 280 m, 520 m, 880 m, 1,320 m, 1,820 m, 2,380 m, 3,000 m, and 4,000 m.

Table D-1 Model Domain (70 km by 48 km) Coordinates (UTM Zone 14; NAD 83)

Domain Corner	Easting (m)	Northing (m)
Southwest	361775	6278500
Northwest	361775	6326500
Northeast	431775	6326500
Southeast	431775	6278500

D.2.2 Topography

The valley and elevated terrain features in the model domain affect surface wind flow patterns. The terrain data used to define these features were obtained from a terrain dataset integrated from Light Detection and Ranging (LiDAR) 5 m resolution data over the project area and U.S. Geological Survey (USGS) Shuttle Radar Topography Mission (SRTM) 30 m resolution data over rest area of CALMET model domain. These data are more than sufficient for air quality assessment purposes for this Project.

A general overview of the terrain in the model domain is presented in Map D-1. Broadly speaking, the higher elevations are towards the west of the domain, and the lowest elevations are near the east portion of the domain.

D.2.3 Land-Cover Types

The North American land-cover data (Commission for Environmental Cooperation 2016) is used to initialize land-cover categories in the CALMET model. The 2005 North American land-cover dataset was produced as part of the North American Land Change Monitoring System (NALCMS), a trilateral effort between the Canada Centre for Remote Sensing, the United States Geological Survey, and three Mexican organizations including the National Institute of Statistics and Geography, National Commission for the Knowledge and Use of the Biodiversity, and the National Forestry Commission of Mexico. This dataset has a 250 m resolution.

For this assessment, the 2005 North American land-cover data were extracted and then converted into the fractional land-use format accepted by the CALMET MAKEGEO pre-processor. MAKEGEO creates the geophysical data file (GEO.DAT) for CALMET. The 250 m resolution data were grouped on a 500 m grid basis and the land-cover type assigned to the larger grid cell is based on the dominant land-cover type for that grid cell.

The mapping from the North American land-cover dataset to the CALMET land-use categories is contained in Table D-2. Tables D-3 to D-6 describe the seasonal values for surface roughness (z_0), albedo, Bowen ratio, soil heat flux, anthropogenic heat flux, and leaf area index (LAI) defined according to the Guidelines for AEP Air Quality Model Guideline (AEP 2013) and the CALMET User Guide (Scire et al. 2000).

Land-cover in the CALMET Domain is mainly evergreen forest (see Map D-2 for the land cover on a 500 m resolution basis). Based on the 500 m resolution data, the domain is comprised of 63.2% evergreen forest, 13.9% water, 8.3% mixed forest, 7.9% shrub rangeland, 5.9% wetland, 0.9% rangeland, and 0.1% barren land.

D.1 METEOROLOGICAL MEASUREMENTS

Meteorological data include a wide range of parameters: ambient air temperature, precipitation, relative humidity, visibility, solar radiation, wind, severe weather, and thermal inversions. Selected parameters at the nearby Environment and Climate Change Canada (ECCC) Lynn Lake Airport climate station are reviewed.

D.1.1 Ambient Air Temperature

Table D-7 summarizes the historical monthly and annual mean air temperatures at the Lynn Lake Airport for the period of 1981 to 2010. The annual average ambient temperature is 3.1°C at this station.

Table D-7 Historical Monthly and Annual Mean Daily Temperatures at Lynn Lake Airport (1981 to 2010)

Month	Mean Daily Temperature (°C)
January	-24.3
February	-20.3
March	-13
April	-3.1
May	5.6
June	12.9
July	16.2
August	14.7
September	7.7
October	-0.6
November	-12.5
December	-21.4
ANNUAL	-3.2
SOURCE: National Climate Data and Information Archive http://climate.weather.gc.ca/climate_normals/index_e.html	

D.1.2 Precipitation

Table D-8 summarizes monthly mean total precipitation, rainfall, and snowfall at the Lynn Lake Airport. The average total precipitation at the Lynn Lake Airport was 477.9 mm/y. The driest months are during the winter, while the wettest month is in July.

Table D-8 Mean Monthly and Annual Total Precipitation, Rainfall, and Snowfall at Lynn Lake Airport (1981 to 2010)

Month	Total Precipitation (mm)	Total Rainfall (mm)	Snowfall (cm)
January	20.3	0.2	27.6
February	16.3	0.1	23.5
March	19.8	1.4	24.6
April	24.1	4.5	23.9
May	37.3	26.7	10.4
June	61.8	60.6	1.3
July	85.4	85.3	0.1
August	68.8	68.7	0.1
September	61	57.4	3.5
October	37.6	12.2	31.3
November	26.8	0.8	36
December	18.8	0.1	26
Annual	477.9	317.9	208.1

D.2 CALMET INPUT DATA

The CALMET model requires the input of surface and upper air meteorological fields. For this application, CALMET was run in Hybrid mode by using surface observations and WRF model output for the period of January 1, 2012, to December 31, 2016. There are no upper air stations within or nearby the CALMET domain.

D.2.1 WRF 12km Data

For this assessment, 12 km grid resolution WRF model data was generated by Stantec for the years 2012 to 2016 and incorporated into the CALMET processing. Map D-3 shows the WRF grid point locations based on 12 km grid resolution within the CALMET model domain.

D.2.2 Surface Observations

For this assessment, there is one hourly surface meteorological station within CALMET domain (shown in Map D-4). The CALMET construct was enhanced by surface meteorological data available at Lynn Lake Airport station. Surface temperature, relative humidity, wind speed and wind direction are the four meteorological parameters included in CALMET modeling.

Figure D-1 shows a wind rose for the Lynn Lake station for the years 2012 to 2016. There is not an overly dominant prevailing wind direction on an annual basis, with similar percent of west, northwest, north, south, and east winds (5 to 7 % of the time for each direction), likely attributable to the local topography near this station.

Title
Location of the Surface Meteorological Station used within the CALMET Model Domain

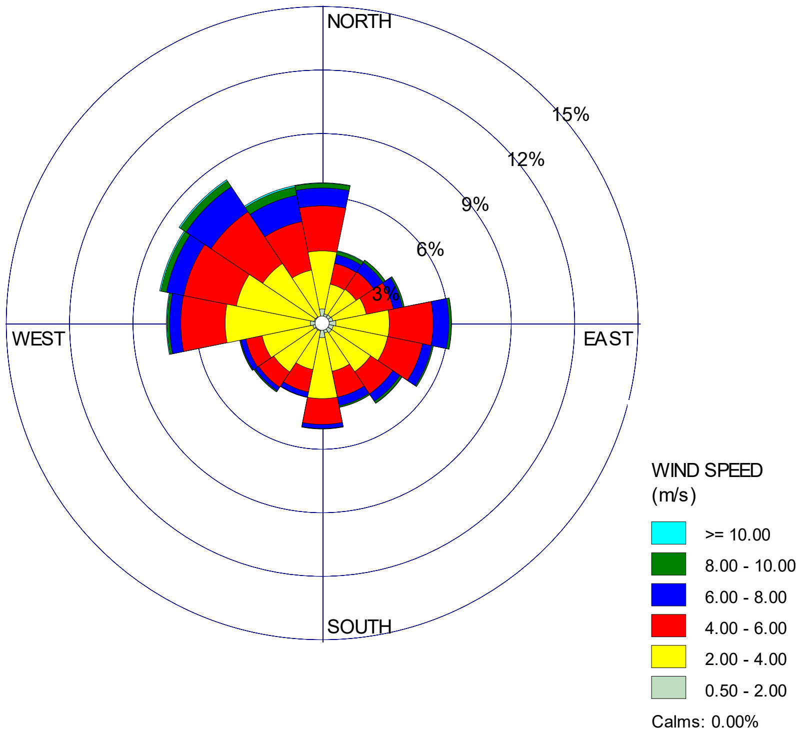

Figure D-1 Measured Wind Rose at Lynn Lake station for the years 2012 to 2016

D.3 WRF DATA QAQC

The meteorological observations from the ECCC Lynn Lake Airport station were used to determine the representativeness of the mesoscale meteorological data, generated using the WRF model. The coordinates of the Lynn Lake Airport station and nearest WRF grid point are provided in Table D-9. The selected WRF grid point is located approximately 5 km west of the Lynn Lake Airport station. Wind speed, wind direction and temperature data at the lowest vertical level in the model were extracted from WRF and compared to the Lynn Lake Airport observations for a five-year period (2012 to 2016).

Figure D-2 compares the wind roses generated for the Lynn Lake Airport to the WRF model predictions from the nearest WRF grid point. As shown, there is general agreement between the measured and WRF predicted wind roses, in that the predominant (most frequent) winds are from northwest, west, north and east. Further, the wind speed class frequency distributions are also in reasonable agreement, in that the most frequent wind speed class is 2.0 to 4.0 m/s.

Figure D-3 compares the monthly average surface air temperatures from the WRF model predictions to measurements at the Lynn Lake Airport station. The WRF model predictions show warm bias during November, December, January and February; however, there is a reasonable agreement with the ECCC Lynn Lake Airport observations throughout the five-year period.

Since the measured values and the WRF model predictions are in reasonable agreement at the Lynn Lake Airport station (within the CALMET model domain) and close to the Project site, the WRF model predictions are reasonably representative of meteorological conditions in the model domain.

Table D-9 Coordinates of Lynn Lake Airport Surface Station and Nearest WRF Grid Point

Location Name	UTM east (m)	UTM north (m)	UTM zone	Latitude (N)	Longitude (W)
Lynn Lake Airport	373182	6303730	14	56.860	101.080
WRF cell	367986	6303445	14	56.856	101.165

Figure D-3 Comparison of Measured and Predicted (WRF) Monthly Average Air Temperature at the Lynn Lake Airport station (2012–2016)

D.4 CALMET PREDICTIONS

To assess the value of the WRF-CALMET model approach for this assessment, the CALMET surface and elevated wind, surface temperature, mixing height, and PG stability class data were extracted for the Gordon and MacLellan Sites for analysis.

D.4.1 Predicted Surface Winds Field

The CALMET model can provide surface wind vector plots for all the grid points across a model domain. Three plots were generated to represent unstable, stable, and neutral conditions for the near-field model domain. The three sample wind vector plots are described below:

- Map D-5 shows the wind field as a vector plot at 1500 LST on July 5, 2016, for convective (i.e., unstable) conditions (PG class B). Winds in the east part of the domain are mainly from northeast, whereas those in the west part of the domain tend to be easterly. The predicted winds at the Project site are mainly from the northeast.

- Map D-6 shows the wind field as a vector plot at 0800 LST on January 6, 2016, for stable conditions (PG class F). Winds are mainly from the northwest and north across most of the domain. The predicted winds at the Project site are mainly from the northwest.
- Map D-7 shows the wind field as a vector plot at 2200 LST on December 13, 2016, for high wind speed (i.e., neutral) conditions. Under these conditions, winds are mainly from the northwest across most of the domain. The predicted winds at the Project site are mainly from the northwest.

The vector plots were not selected to represent a specific meteorological condition; they are provided to show the variability of the airflow that can occur over the 50 km by 50 km area during any given hour. Departures of the predicted vector plots from the actual wind field for a given hour are to be expected given the nature of modelling and the relatively low density of actual observations across the region. The predicted values, however, are preferable to assuming a homogeneous wind field across the domain for each hour, based on the local terrain influences that are reflected in the measured data.

Title
Predicted Surface Wind Field for High Wind Conditions (2200 LST December 13, 2016)

D.4.2 Predicted Winds at Project Sites

Figures D-4 and D-5 show wind roses predicted by CALMET for the two Project sites at various elevations above the ground (i.e., 10 m, 60 m, 100 m and 200 m). The results indicate:

- At all four levels, winds are mainly from northwest, west, and north. Higher winds are mainly from northwest.
- Wind speed increases with increasing height above the ground.

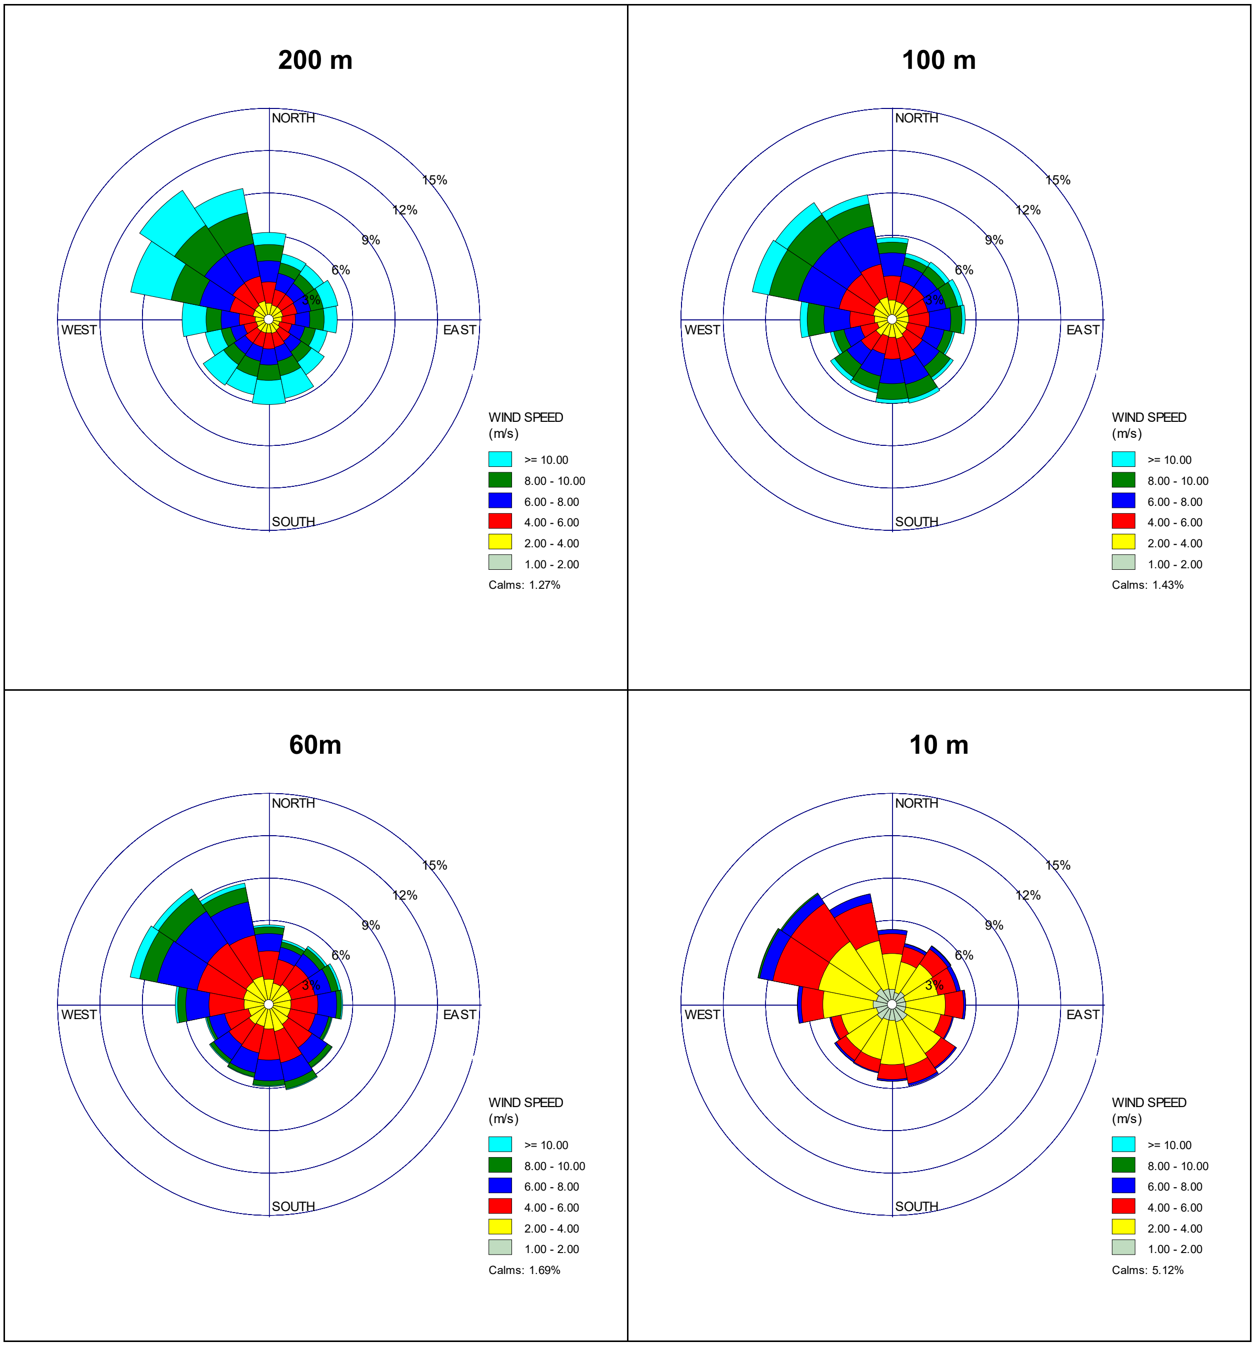

Figure D-4 Predicted Elevated Level Wind Roses for the Gordon Site (2012 to 2016)

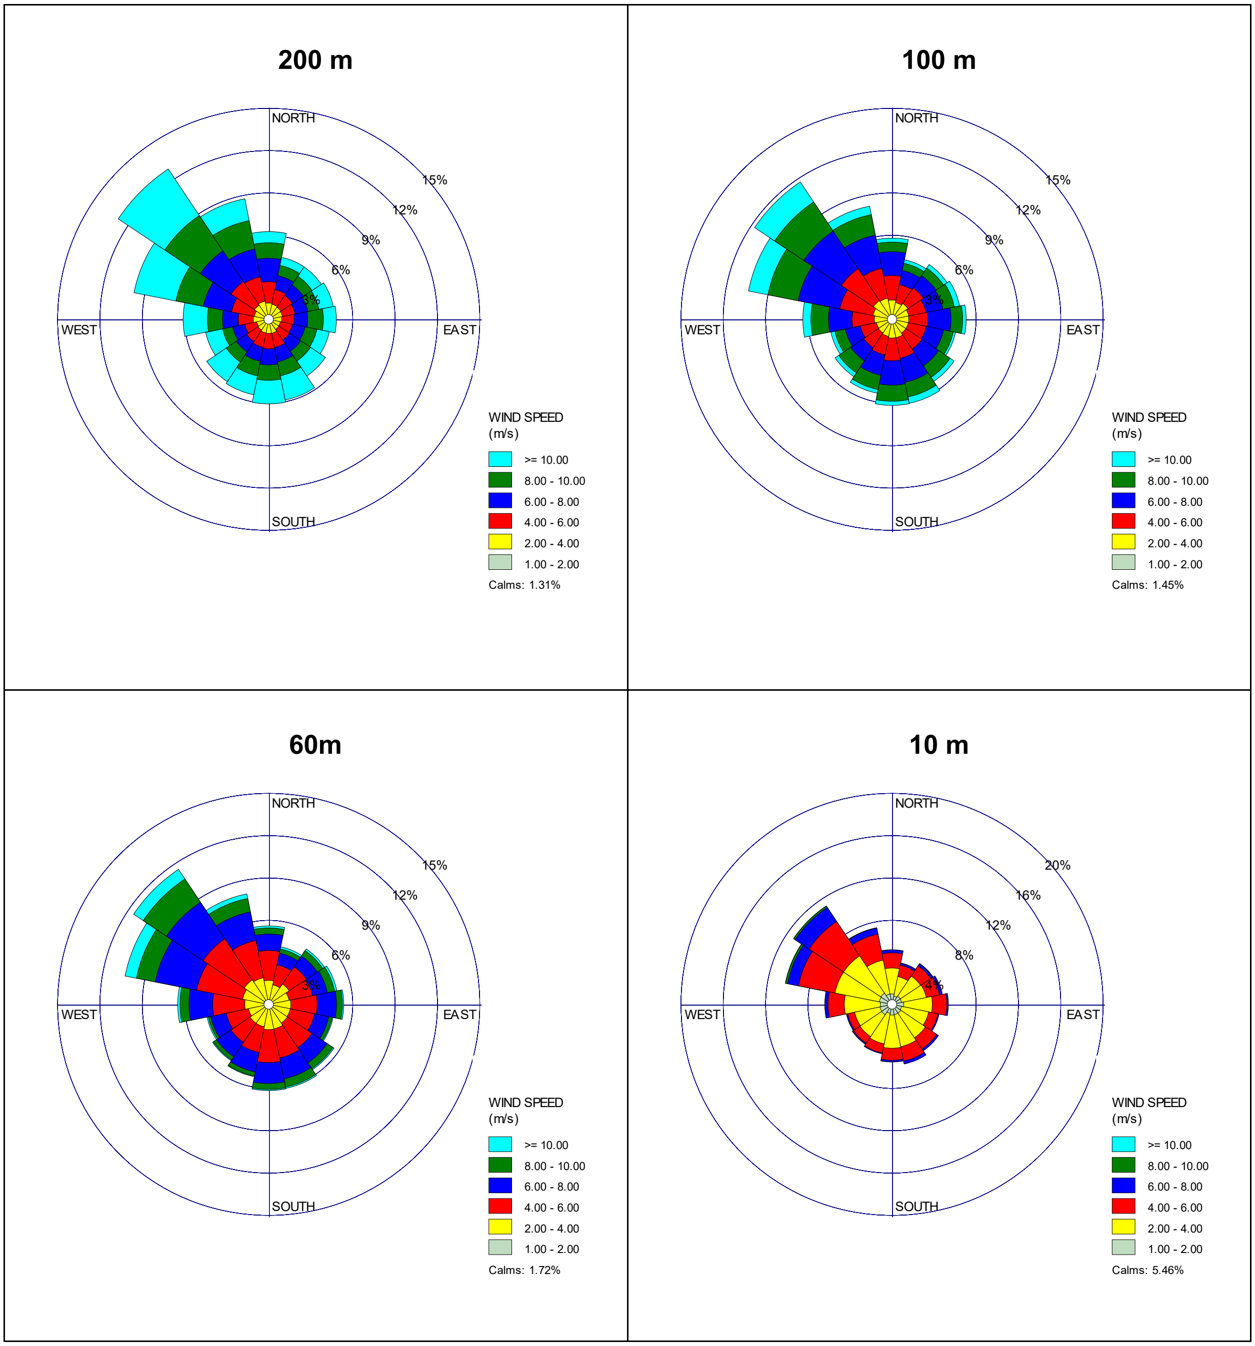

Figure D-5 Predicted Elevated Level Wind Roses for the MacLellan Site (2012 to 2016)

D.4.3 Predicted Surface Temperatures

Figures D-6 and D-7 show the monthly average surface temperatures predicted by CALMET for the Gordon and MacLellan sites, respectively. The predicted monthly temperatures indicate reasonable seasonal surface temperature variations (i.e., compare with Table D-7).

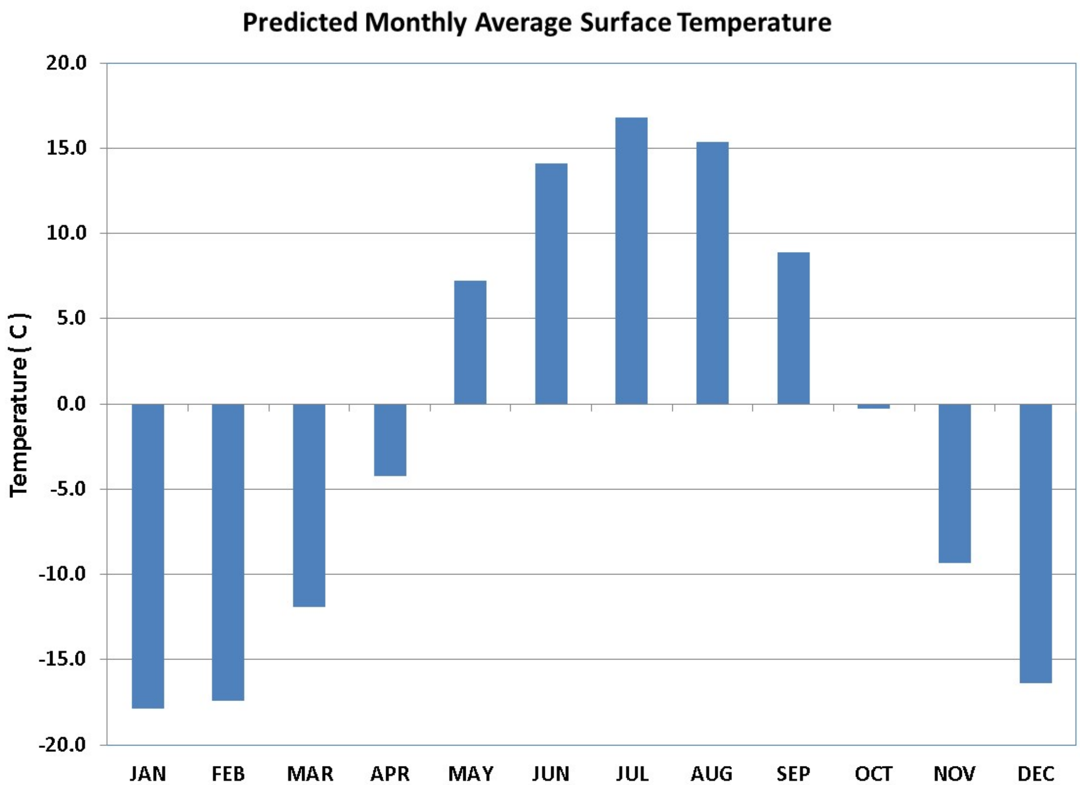

Figure D-6 Predicted Monthly Average Surface Temperatures for the Gordon Site (2012 to 2016)

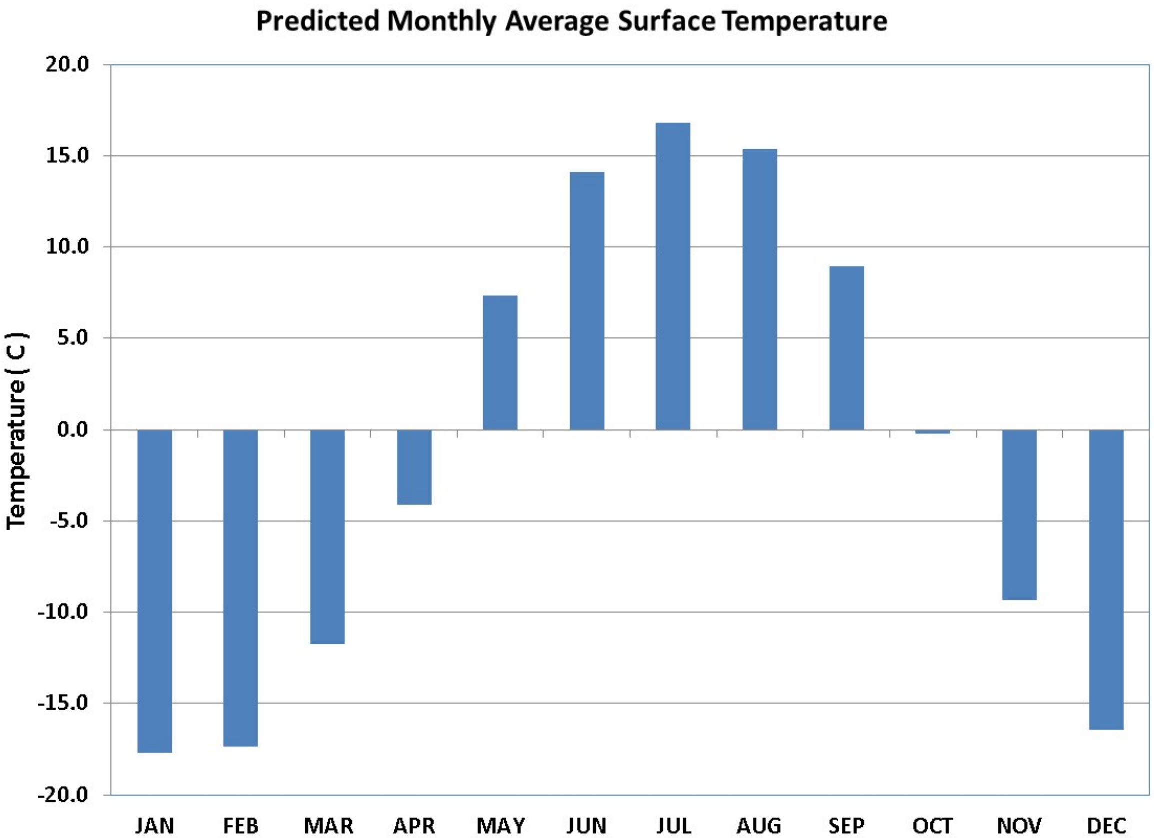

Figure D-7 Predicted Monthly Average Surface Temperatures for the MacLellan Site (2012 to 2016)

D.4.4 Predicted Mixing Heights

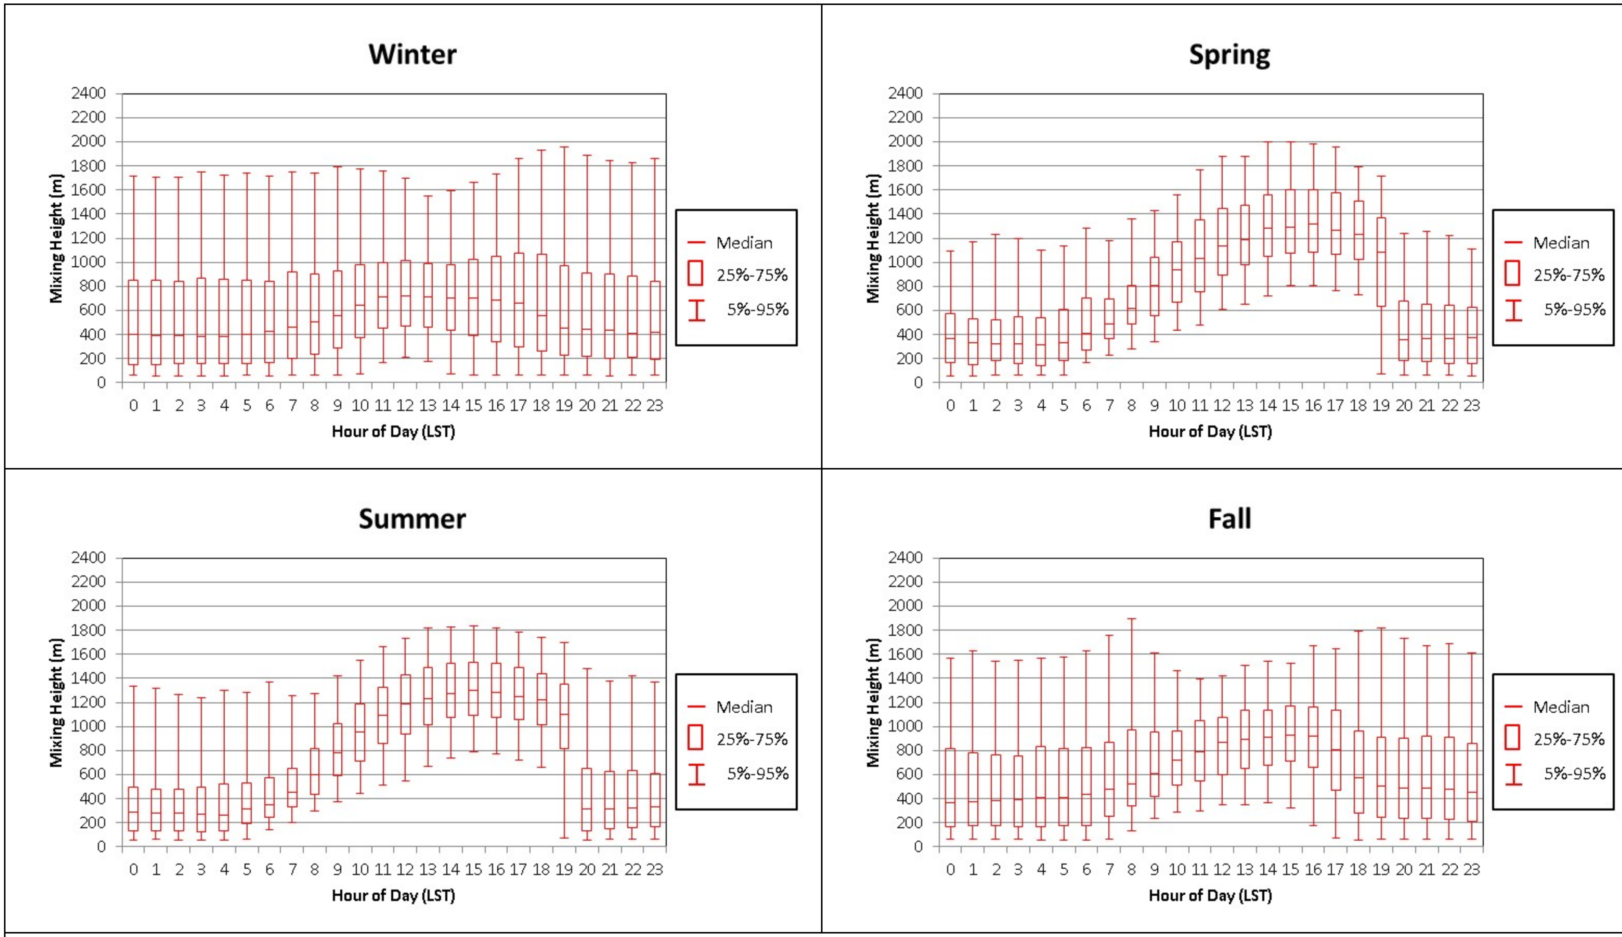
The presence of an elevated inversion can trap effluents discharged into the atmosphere in the layer between the surface and the base of the inversion layer; this can increase ground-level ambient concentrations relative to the absence of an inversion layer. Mixing heights are usually the highest (i.e., in the 1,000 m to 2,000 m range) during daytime periods that are characterized by strong solar heating, and the lowest (i.e., about 100 m) during the night. High wind speeds can also produce well-mixed layers.

For this assessment, the CALMET post-processor was used to extract the mixing heights from CALMET output files, and the mixing height predictions for the Gordon and MacLellan Sites are provided in Figures D-8 and D-9, respectively. The results show:

- Winter: The maximum median values are about 800 m and 793 m at Gordon and MacLellan Sites, respectively.

- Spring: The maximum median afternoon values are about 1,342 m and 1,273 m at Gordon and MacLellan Sites, respectively.
- Summer: The maximum median afternoon values are about 1,310 m and 1,236 m at Gordon and MacLellan Sites, respectively.
- Fall: The maximum median afternoon values are about 941 m and 909 m at Gordon and MacLellan Sites, respectively.

The minimum values for each season are predicted to occur during the night. During the night, the mixing height tends to be determined by mechanical mixing processes, with higher wind speeds resulting in a deeper mixed layer. The convective mixing process dominates during the day, leading to maximum mixed layer depths during the afternoon. The CALMET model, as applied, sets the minimum mixing height to 50 m.



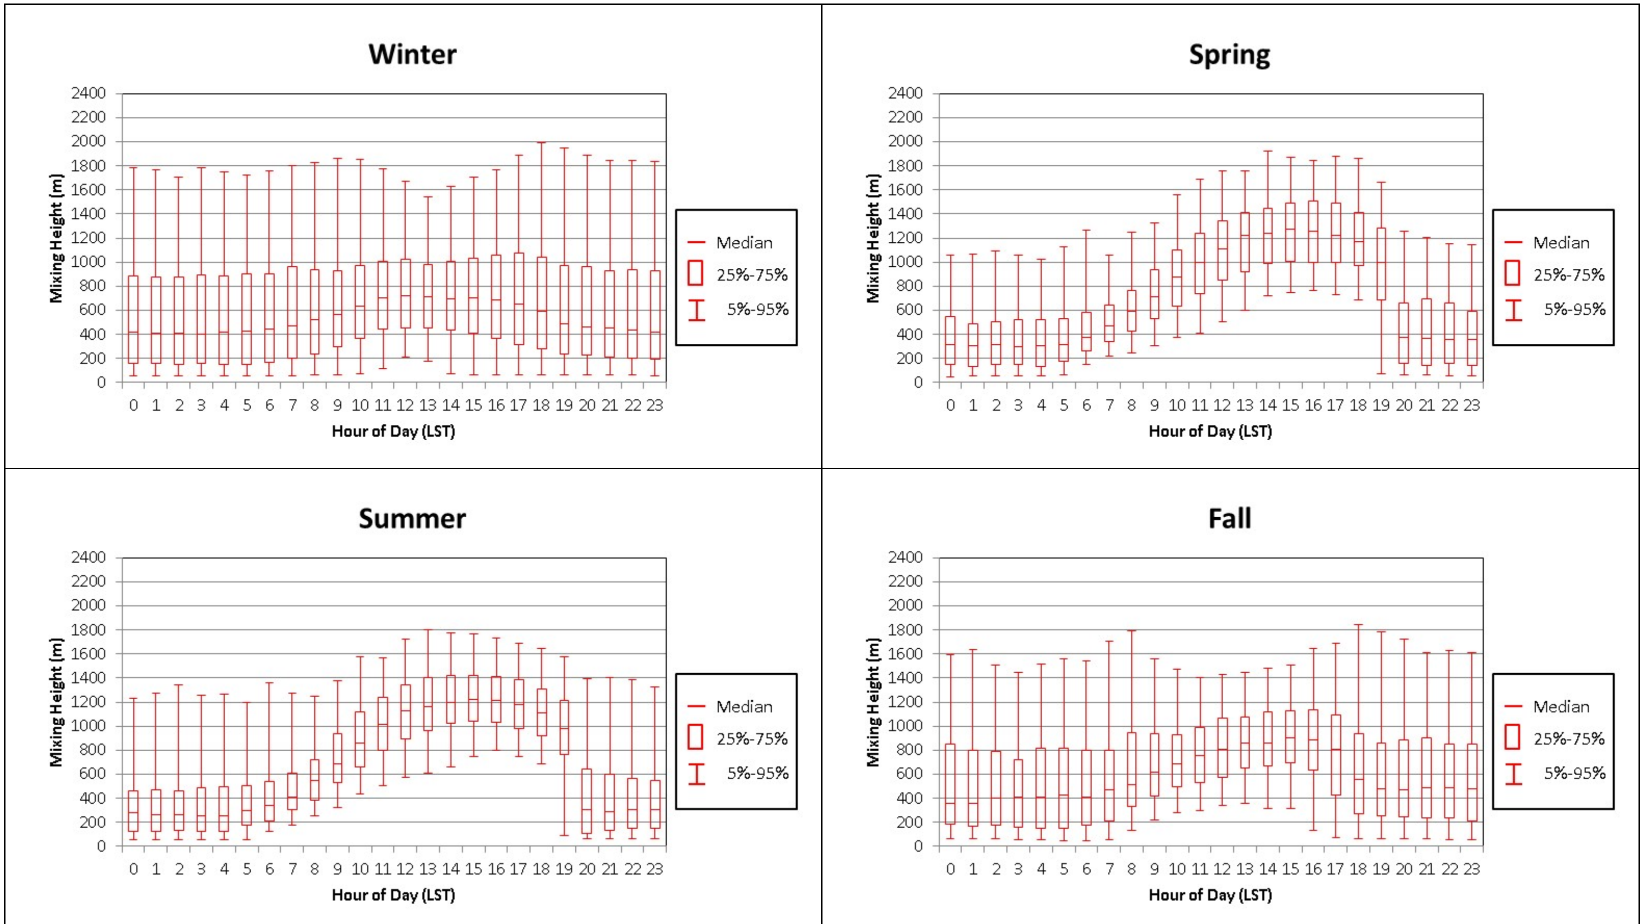
NOTE: **Winter**: November, December, January, February, March, and April.

Summer: June, July, and August.

Spring: May.

Fall: September and October

Figure D-8 Predicted Mixing Heights for Different Seasons and Times of Day for the Gordon Site (2012 to 2016)



NOTE: **Winter**: November, December, January, February, March, and April.

Summer: June, July, and August.

Spring: May.

Fall: September and October

Figure D-9 Predicted Mixing Heights for Different Seasons and Times of Day for the MacLellan Site (2012 to 2016)

D.2.4 Predicted Atmospheric Stability Class

Atmospheric dispersion is caused by atmospheric turbulence, which can be related to atmospheric stability. Meteorologists define six stability classes (referred to as the Pasquill Gifford [PG] classes):

- Stability classes A, B and C occurs during the day, when solar radiation heats the ground. The air next to the ground is heated and tends to rise, enhancing vertical motions. This is referred to as an unstable atmosphere.
- Stability classes E and F occur during the night, when the ground cools due to long-wave radiation losses. The air next to the ground cools, suppressing vertical motions. This is referred to as a stable atmosphere.
- Stability class D is associated with completely overcast conditions (day or night) when there is no net heating or cooling of the ground, transitional periods between stable and unstable conditions, or during high wind speed periods (winds greater than 6 m/s [or 22 km/h]). This is referred to as a neutral atmosphere.

Stability classes undergo a significant daily variation, and they have a seasonal dependence. Stability classes can be determined from routine airport observations using the method devised by Turner (1963). A stability classification algorithm is also included in the CALMET model, this approach is based on the Turner approach using wind speed and cloud cover information for each grid point in the domain.

Table D-10 compares the stability class frequency distributions based on the CALMET model predictions for the Project Site. Figures D-10 and D-11 presented the frequency distributions of predicted seasonal PG stability classes on a diurnal basis for the Gordon and MacLellan Sites, respectively. Unstable conditions are more frequent during the summer, and during daytime periods. Stable conditions are more frequent during nighttime periods.

Table D-10 Predicted Stability Class Frequency Distributions (%) at the Project Site (2012 to 2016)

PG Class	Gordon Site	MacLellan Site
A	0.3	0.3
B	8.7	8.6
C	15.8	15.5
D	36.7	38.4
E	13.0	13.0
F	25.5	24.4
Total	0.3	0.3

NOTE:

D.1 CALMET MODEL OPTIONS

The input parameters for the CALMET control file used for the assessment are provided in Tables D-11 to D-18. The AEP Air Quality Model Guideline (AEP 2013) indicates that default assumptions and switches are to be used. Although not specified in the Model Guideline, it is assumed that the default values are defined in the CALMET user manual (Scire et al. 2000). The Model Guideline also indicates some specific values that are to be used instead of the default values; the AEP values are highlighted by orange shading in the tables. All AEP recommended default switch selections were applied. The default values and the values adopted for this assessment are identified in the tables.

Table D-11 Input Groups in the CALMET Control File

Input Group	Description	Applicable to Project
0	Input and output file names	Yes
1	General run control parameters	Yes
2	Grid control parameters	Yes
3	Output Options	Yes
4	Meteorological data options	Yes
5	Wind Field Options and Parameters	Yes
6	Mixing Height, Temperature and Precipitation Parameters	Yes
7	Surface meteorological station parameters	Yes
8	Upper air meteorological station parameters	No
9	Precipitation parameters	No

ISLOPE	1	1	Compute slope flow effects
IEXTRP	-4	1	no extrapolation is done
ICALM	0	0	Extrapolate surface winds even if calm
BIAS	NZ*0	12*0	Layer-dependent biases modifying the weights of surface and upper air stations Zero BIAS leaves weights unchanged
RMIN2	4	4	Minimum distance from nearest upper air station to surface station for which extrapolation of surface winds at surface station will be allowed
IPROG	14	14	Use gridded prognostic wind field model output fields as input to the diagnostic wind field model. Set to 14 as WRF gridded model data was used as the main input to CALMET model for this assessment. As per the AEP Model Guideline.
ISTEPPGs	3600	3600	Time step (seconds) of the prognostic model input data
IGFMET	0	0	Use coarse CALMET fields as initial guess fields
Radius of Influence Parameters:			
LVARY	F	F	Use varying radius of influence
RMAX1	6	6	Maximum radius of influence over land in the surface layer (km)
RMAX2	24	Not Applicable	Maximum radius of influence over land aloft (km)
RMAX3	24	Not Applicable	Maximum radius of influence over water
Other Wind Field Input Parameters:			
RMIN	0.1	0.1	Minimum radius of influence used in the wind field interpolation (km)
TERRAD	-	3	Radius of influence of terrain features (km) based on local topographic conditions near the Project Site
R1	-	2	Relative weighting of the first guess field and observations in the surface layer (km)
R2	6	Not Applicable	Relative weighting of the first guess field and observations in the layers aloft (km)
RPROG	-	0	Relative weighting parameter of the prognostic wind field data (km)
DIVLIM	5.0E-6	5.0E-6	Maximum acceptable divergence in the divergence minimization procedure

Table D-16 CALMET Model Option Group 5: Wind Field Options and Parameters

Parameter	Default	Project	Comment
NITER	50	50	Maximum number of iterations in the divergence minimization procedure
NSMTH (NZ)	2, (MXNZ-1)*4	2, 11*4	Number of passes in the smoothing procedure For NZ level 1, the CALMET default value 2 was used for the Project. For other levels, value 4 was used as CALMET input 12km WRF data already provided spatial wind fields
NINTR2	99	12*99	Maximum number of stations used in each layer for the interpolation of data to a grid point
CRITFN	1.0	1.0	Critical Froude number
ALPHA	0.1	0.1	Empirical factor controlling the influence of kinematic effects
FEXTR2(NZ)	NZ*0.0	12*0	Multiplicative scaling factor for extrapolation of surface observations to upper layers
Barrier Information:			
NBAR	0	0	Number of barriers to interpolation of the wind fields (The barrier option is not used)
KBAR	NZ	12	Level (1 to NZ) up to which barriers apply For this project, NZ=12
XBBAR	-	0	X coordinate of beginning of each barrier
YBBAR	-	0	Y coordinate of beginning of each barrier
XEBAR	-	0	X coordinate of ending of each barrier
YEBAR	-	0	Y coordinate of ending of each barrier
Diagnostic Module Data Input Options:			
IDIOPT1	0	0	Surface temperature (0 = compute internally from hourly surface observation)
ISURFT	-	-1	use 2-D spatially varying surface temperatures
IDIOPT2	0	0	Domain-averaged temperature lapse (0 = compute internally from hourly surface observation)
IUPT	-	Not Applicable	Not applicable since no upper air stations are used
ZUPT	200	200	Depth through which the domain-scale lapse rate is computed (m)
IDIOPT3	0	0	Domain-averaged wind components
IUPWND	-1	Not Applicable	Not applicable since no upper air stations are used
ZUPWND	1., 1000	Not Applicable	Bottom and top of layer through which domain-scale winds are computed (m). Not applicable since it is only used if IDIOPT3 = 0, NOOBS > 0 and IUPWND > 0
IDIOPT4	0	0	Observed surface wind components for wind field module
IDIOPT5	0	Not Applicable	Observed upper air wind components for wind field module
Lake Breeze Information:			
LLBREZE	F	F	Lake breeze module is not used

Table D-16 CALMET Model Option Group 5: Wind Field Options and Parameters

Parameter	Default	Project	Comment
NBOX	-	0	Number of lake breeze regions
XG1	-	0	X Grid line 1 defining the region of interest
XG2	-	0	X Grid line 2 defining the region of interest
YG1	-	0	Y Grid line 1 defining the region of interest
YG2	-	0	Y Grid line 2 defining the region of interest
XBCST	-	0	X Point defining the coastline in kilometres (Straight line)
YBCST	-	0	Y Point defining the coastline in kilometres (Straight line)
XECST	-	0	X Point defining the coastline in kilometres (Straight line)
YECST	-	0	Y Point defining the coastline in kilometres (Straight line)
NLB	-	0	Number of stations in the region
METBXID	-	0	Station ID’s in the region

Table D-17 CALMET Model Option Group 6: Mixing Height, Temperature and Precipitation Parameters

Parameter	Default	Project	Comment
Empirical Mixing Height Constants:			
CONSTB	1.41	1.41	Neutral, mechanical equation
CONSTE	0.15	0.15	Convective mixing height equation
CONSTN	2400	2400	Stable mixing height equation
CONSTW	0.16	0.16	Over water mixing height equation
FCORIO	1.0E-4	1.0E-04	Absolute value of Coriolis parameter
Spatial Averaging of Mixing Heights:			
IAVEZI	1	1	Conduct spatial averaging
MNMDAV	1	1	Maximum search radius in averaging (grid cells)
HAFANG	30	30	Half-angle of upwind looking cone for averaging
ILEVZI	1	1	Layer of winds used in upwind averaging
Convective Mixing Heights Options:			
IMIXH	1	1	Method to compute the convective mixing height (Maul-Carson)
THRESHL	0.0	0.0	Threshold buoyancy flux required to sustain convective mixing height growth overland (W/m^3)
THRESHW	0.05	0.05	Threshold buoyancy flux required to sustain convective mixing height growth overwater (W/m^3)
IZICRLX	1	1	Flag to allow relaxation of convective mixing height to equilibrium value when 0<QH<THRESHL (overland) or 0<QH<THRESHW (overwater)

Table D-17 CALMET Model Option Group 6: Mixing Height, Temperature and Precipitation Parameters

Parameter	Default	Project	Comment
TZICRLX	800	800	Relaxation time of convective mixing height to equilibrium value Used only if IZICRLX = 1 and TZICRLX must be >= 1.
ITWPROG	0	0	Option for overwater lapse rates used in convective mixing height growth (1=use prognostic lapse rates)
ILUOC3D	16	16	Land use category ocean in 3D.DAT datasets
Other Mixing Height Variables:			
DPTMIN	0.001	0.001	Minimum potential temperature lapse rate in the stable layer above the current convective mixing height (K/m)
DZZI	200	200	Depth of layer above current convective mixing height through which lapse rate is computed (m)
ZIMIN	50	50	Minimum overland mixing height (m)
ZIMAX	3,000	4,000	Maximum overland mixing height (m) Increased to 4000 m to consistent with AEP recommended model layers which the highest ZFACE is 4000 m
ZIMINW	50	50	Minimum overwater mixing height (m)
ZIMAXW	3,000	4,000	Maximum overwater mixing height (m) Increased to 4000 m to consistent with AEP recommended model layers which the highest ZFACE is 4000 m
Overwater Surface Fluxes Method and Parameters:			
ICOARE	10	10	Overwater surface fluxes method Set to 10 means COARE with no wave parameterization
DSHELF	0	0	Coastal/Shallow water length scale (km)
IWARM	0	0	COARE warm layer computation
ICOOL	0	0	COARE cool skin layer computation
Relative Humidity Parameters:			
IRHPROG	1	1	Use the WRF gridded relative humidity data as per the AEP Model Guideline.
Temperature Parameters:			
ITPROG	-	2	No surface or upper air observations Use the WRF gridded surface temperature data as per the AEP Model Guideline.
IRAD	1	1	Interpolation type
TRADKM	24	24	Radius of influence for temperature interpolation (km) to be set at two times the WRF 12 km resolution as per the AEP Model Guideline
NUMTS	5	Not Applicable	Maximum number of stations to include in temperature interpolation
IAVET	1	1	Conduct spatial averaging of temperatures (1 = yes)

Table D-17 CALMET Model Option Group 6: Mixing Height, Temperature and Precipitation Parameters

Parameter	Default	Project	Comment
TGDEFB	-0.0098	-0.0098	Default temperature gradient below the mixing height over water (K/m)
TGDEFA	-0.0045	-0.0045	Default temperature gradient above the mixing height over water (K/m)
JWAT1	-	55	Beginning land use categories for temperature interpolation over water
JWAT2	-	55	Ending land use categories for temperature interpolation over water
Precipitation Interpolation Parameters:			
NFLAGP	2	Not Applicable	Method of interpolation
SIGMAP	100	Not Applicable	Radius of Influence (km) Not Applicable for this project as no precipitation station data were used
CUTP	0.01	Not Applicable	Minimum Precipitation rate cut-off (mm/h)

E.1 INTRODUCTION

Ambient air quality models are used to predict air quality changes (i.e., changes to ambient concentrations or deposition) associated with current and future emission scenarios. This section discusses the selection and application of the primary dispersion model that was used for the Lynn Lake Gold Project (the Project) air quality assessment.

E.1.1 Model Types

Air quality simulation (or dispersion) models provide a scientific means of relating industrial and community emissions to air quality changes, by using mathematical equations to simulate transport, dispersion, transformation, and deposition processes in the atmosphere. Dispersion models can address a wide range of distance scales (hundreds of metres to hundreds of kilometres) and time scales (minutes to years). Typically, there are two modelling levels-of-effort:

- **Screening models** that estimate maximum short-term (1-hour) average concentrations for a wide range of pre-selected meteorological conditions. These models are typically limited to single sources and downwind distances of less than 10 km (e.g., the US Environmental Protection Agency [US EPA] SCREEN3 and AERSCREEN models).
- **Refined models** that use sequential hourly meteorological data for a one to five-year period (8,760 hours to 43,800 hours, respectively). These models can address multiple sources, and predict hourly average concentrations for all source, meteorology, and receptor combinations. The hourly concentrations can be used to predict concentrations for averaging periods that are factors of 24 (i.e., 2, 3, 4, 6, 8, or 12 h), or for longer periods (i.e., seasonal or annual). Some refined models can also account for chemical transformation and deposition processes.

Regulatory agencies rely on dispersion models as part of the approval process for a variety of industrial projects. Numerous models are available to predict ambient air quality changes and the appropriate selection depends on project-specific circumstances. In response to the regulatory use of these models, formal guidelines regarding the selection and application of these models have been developed (e.g., Manitoba Conservation (2006); Ontario Ministry of the Environment and Climate Change (MOECC) 2016; US EPA 2005a; British Columbia Ministry of Environment (BC MOE 2015); Alberta Environment and Sustainable Resource Development [ESRD] 2013).

E.1.2 Model Input/Output Files

The application of a dispersion model requires the preparation of input files and the analysis of output files. The input files include the following:

- control/option information to identify the model run, to select the available technical features, and to control the output options specific to the selected model
- source data that identify the locations, emission characteristics (e.g., stack height), and emission rates (e.g., oxides of nitrogen [NO_X] emission rate) for each source
- terrain elevations and surface characteristics to account for terrain influences on airflow and turbulence
- surface characteristics to provide the deposition properties for the vegetation canopy
- meteorological data on an hourly basis to characterize airflow and turbulence in the region

The output files can include:

- a summary file to identify the model run and to provide an overview of the run inputs
- hourly predicted concentration files for each receptor and meteorological combination
- hourly predicted deposition files for each receptor and meteorological combination

Presentation and graphical software are used to re-format the model predictions and to provide concentrations and deposition contour plots that can be superimposed over base maps to illustrate predictions within the modelled domain.

E.2 MODEL SELECTION

E.2.1 Requirements

For the Project assessment, the selected model should have the ability to account for:

- multiple point, area, and volume sources
- flat and elevated terrain features
- multiple species in one model simulation
- wet, dry, gaseous, and particulate deposition processes

These features are required to predict ambient concentrations and deposition. Furthermore, the model selection and application needs to be consistent with the Manitoba Air Quality Model Guideline (AQMG) (Manitoba Conservation 2006).

E.2.2 Selected Model

Based on the review of the AQMG, the CALPUFF model (Version 7.2.1, Level 150618) was selected since it can be used to model multiple species, multiple source types and provides deposition outputs. CALPUFF has two options with respect to meteorological data:

- The simple mode assumes a uniform meteorological field over the model domain during a given hour. However, CALPUFF has the advantage of allowing the plume trajectories to vary from hour-to-hour in a systematic manner as the wind direction varies from hour-to-hour. This becomes more important to include when the model is applied to larger domains.
- The CALMET mode allows for three-dimensionally varying meteorological fields over the model domain during a given hour.

For this assessment, the CALPUFF model with the three-dimensional CALMET meteorological data fields was selected (see Appendix D).

E.2.3 CALPUFF Model Assumptions

The CALPUFF model (Scire et al. 2000) is a multi-layer, multi-species, non-steady state puff dispersion model that can simulate the effects of time and space-varying meteorological conditions on substance transport, transformation, and removal. CALPUFF contains algorithms for near-source effects such as building downwash, transitional plume rise, partial plume penetration, as well as longer-range effects such as chemical transformation, and pollutant removal (wet scavenging and dry deposition). It can accommodate arbitrarily varying point source and area source emissions. Most of the algorithms contain options to treat physical processes at differing levels of detail depending on the requirements for the particular model application:

- **Atmospheric Dispersion**: several options are provided in CALPUFF for the computation of dispersion coefficients:
  - similarity theory to estimate σ_v and σ_w from surface heat and momentum fluxes provided by CALMET
  - Pasquill-Gifford (PG) or McElroy-Pooler (MP) dispersion coefficients
  - dispersion equations based on the Complex Terrain Dispersion Model (CTDM)
  - hourly values of direct turbulence measurements (σ_v and σ_w)
- **Chemical Transformation**: CALPUFF includes options to parameterize chemical transformation effects using the five species scheme (SO_2, SO_4^{2-}, NO_X, nitric acid [HNO_3], and NO_3^-) employed in the MESOPUFF II model, a modified six-species scheme (SO_2, SO_4^{2-}, NO, NO_2, HNO_3, and NO_3^-) adapted from the RIVAD/ARM3 (Regional Impact in Visibility and Acid Deposition/Acid Rain Mountain Mesocale Model) method, a set of user specified, diurnally-varying transformation rates, or ISORROPIA, an inorganic aerosol thermodynamic equilibrium model that can be used to improve the nitric acid/nitrate aerosol partition.

- **Dry Deposition**: A full resistance model is provided to calculate dry deposition rates of gases and particulate matter as a function of geophysical parameters, meteorological conditions, and substance properties. Options are provided to allow user-specified, diurnally varying deposition velocities to be used for one or more pollutants instead of the resistance model (e.g., for sensitivity testing) or to bypass the dry deposition model completely.
- **Wet Deposition**: An empirical scavenging coefficient approach is used in CALPUFF to compute the depletion and wet deposition fluxes due to precipitation scavenging. The scavenging coefficients are specified as a function of the pollutant and precipitation type (i.e., frozen vs. liquid precipitation).

The following section describes the application of the CALPUFF model specific to the Lynn Lake Gold Mine Project assessment.

E.3 MODEL APPLICATION

E.3.1 Model Domain

The CALPUFF model requires the user to define the area where emissions sources are characterized, the meteorological conditions are characterized, and the locations where the air quality changes are to be predicted. The CALPUFF model domain for this Project is a 28 km by 50 km area, which is further divided into two halves; a 14 km by 25 km area surrounding MacLellan mine site and 14 km by 25 km area surrounding Gordon mine site. This study area includes the communities of Lynn Lake and Black Sturgeon Reserve. The model domain also includes provincial highway 391 which will be used by trucks to transport material from Gordon mine site to the processing plant at Maclellan site. This area is also referred to as the Local Assessment Area (LAA). Table E-1 provides the corners of the LAA.

Table E-1 Local Assessment Area Coordinates (UTM Zone 14; NAD 83)

	Easting (m)	Northing (m)
Model Domain		
Southwest Corner	371775	6288500
Northwest Corner	371775	6316500
Northeast Corner	421775	6316500
Southeast Corner	421775	6288500

E.3.2 Receptor Locations

Two types of receptors within the model domain are defined; gridded Cartesian receptor points and discrete receptor locations.

1. Gridded Cartesian Receptors

A nested grid of receptors following the spacing requirements in the Draft Guidelines for Air Dispersion Modelling in Manitoba (Manitoba Conservation 2006) and the Air Dispersion Modelling Guideline for Ontario (MOECC 2016) is used in the model. The receptors are based on the following spacing:

- 20 m spacing along the Project boundary at Gordon and MacLellan sites
- 100 m spacing along the Project boundary around the access roads to Gordon and MacLellan sites
- 250 m spacing along the Project boundary around PR391.
- 50 m spacing within 500 m of the Project boundary
- 100 m spacing within 1.3 km of the Project boundary
- 200 m spacing within 2.1 km of the Project boundary
- 500 m spacing within 6.9 km of the Project boundary
- 1,000 m spacing beyond 6.9 km of the Project boundary

The grid density is the greatest nearest to the Project as that is where highest concentrations would occur. More distant from the Project, the resolution is sufficient to determine the additive effects of the Project emissions with emissions from other sources. Gridded receptors with a 250-m spacing within the Project fenceline are also included. These receptors are used to plot isopleths within the fenceline but were not used to determine maximum predicted concentrations within the assessment area.

The above indicated spacing is depicted in Map A-8 in Appendix A and the Project centric receptor grid is viewed as being sufficient to provide an indication of the magnitude and spatial concentrations due to Project emissions. The described grid consists of 16,101 receptor points.

2. Discrete Receptors

In addition to gridded receptors, 242 discrete locations corresponding to specific sites of interest (e.g., residences, businesses, traditional land use sites, permanent worker camps etc.) are included. Map A-3 of Appendix A shows the locations and Table E-2 provides the coordinates of these discrete receptors.

E.3.3 Meteorology

The CALMET meteorological model is used to provide representative wind, temperature, and turbulence fields. Five years (2012 to 2016) of hourly CALMET input files were prepared and used for this assessment. The meteorological inputs reflect seasonal variations in the land cover properties. The CALMET modelling is described in detail in Appendix D.

E.3.4 Dispersion

The CALPUFF model offers several dispersion options. Manitoba AQMG and Ontario AQMG do not provide specific guidance for selection of dispersion options. Ontario AQMG refers to US EPA Interagency Work group on Air Quality Modelling (IWAQM) Phase 2 report (US EPA 1998) or any more recent recommendations for guidance on selecting dispersion options. US EPA model recommendations (US EPA 1998) are specific to long range transport and in many cases not appropriate for the assessment where primary objective is near project predictions. CALPUFF model options recommended by Alberta and BC model guideline were used to select dispersion model options for current assessment. The following identifies the dispersion options that were selected for this assessment:

- The selection of the similarity scaling approach to estimate σ_v and σ_w is viewed as using a more up-to-date understanding of dispersion in the boundary layer than the historical discrete PG dispersion approach. The similarity approach treats dispersion as a continuous function, whereas the PG approach considers discrete classes. For this reason, MDISP = 2 (Input group 2) was used to select the similarity approach.

- The Probability Distribution Function (PDF) approach accounts for downdrafts and updrafts that occur under convective conditions. The PDF approach increases the predicted concentrations resulting from stacks under convective conditions. For this assessment MPDF = 1 (PDF assumed) was selected.
- Vertical wind shear accounts for the enhanced dispersion that can happen when the wind direction changes with increasing height above the ground. If vertical wind shear is adopted (MSHEAR = 1), the ambient predicted concentrations can be larger than if vertical wind shear is not simulated (MSHEAR = 0). Scire (2009, pers. comm.), the developer of the CALPUFF model, indicates that there may be some problems with the vertical wind shear algorithms, and he recommends that MSHEAR = 0 be adopted until the issue can be further explored and evaluated. For this reason, the default MSHEAR = 0 (Input group 2) was selected.

This discussion has been provided to indicate the selection of the dispersion details can have an influence on the model predictions. The options that were selected are considered appropriate for the Project and conform with best practice guidance.

E.3.5 Chemical Transformation and Formation of Secondary $PM_{2.5}$

The formation of secondary particulate matter is not considered significant compared to fugitive dust generated from mining activities. Therefore, chemical transformation of NO_x/SO_2 and secondary formation of fine particulate matter was not modelled for this assessment. Therefore, for this assessment MCHEM = 0 was selected.

E.3.6 NO to NO_2 Conversion

Oxides of nitrogen (NO_X) are comprised of nitric oxide (NO) and nitrogen dioxide (NO_2). Only NO_2 concentrations are regulated by the ambient air quality criteria. Therefore, it is important to be able to estimate the portion of predicted ground-level concentrations of NO_X comprised of NO_2. For this current study, the Ozone Limiting Method (OLM) was applied. The OLM is the alternative if adequate monitoring data of NO/NO_2 ratios are not available.

The OLM assumes that the conversion of NO to NO_2 in the atmosphere is limited by the ambient O_3 concentration in the atmosphere. The approach assumes that 10 percent (on a volume basis) of the NO_x is converted to NO_2 prior to discharge into the atmosphere. For the remaining NO_x, the following is adopted:

- If 0.9 (NO_x) is greater than the ambient O_3 concentration then NO_2 = 0.1 (NO_x) + O_3. For this case, the conversion of NO_X to NO_2 is not complete.

- If 0.9 (NO_x) is less than the ambient O_3 concentration then
  NO_2 = 0.1 (NO_x) + 0.9 (NO_x) =NO_x. This is equivalent to the total conversion approach, since there is sufficient O_3 to effect the complete conversion.

As no onsite ozone data is available, ozone measurements from Fort Smith monitoring station in Northwest Territories were used in the OLM conversion. The Fort Smith station is considered the most representative for the LAA as the station is in a similarly remote area with low population density and with similar meteorological and topographical conditions. Hourly ozone data from Fort Smith station was downloaded for the three-year period 2016 to 2018. Hourly time-series of ozone values were compiled using the maximum measured ozone concentration for each hour from the three-year period. Therefore, the hourly ozone time-series used in the OLM conversion are conservative. The maximum ozone concentration measured for the three-year period from 2016 to 2018 was 71 ppb.

E.3.7 Building Downwash

Buildings or other solid facility structures may affect the flow of air in the vicinity of a source and cause building downwash effects due to eddies on the downwind side. These eddies have potential to reduce plume rise and affect dispersion. For this assessment, point sources are potentially affected by building downwash.

Building downwash effects were considered for all stack emissions using the US EPA Building Profile Input Program (BPIP; US EPA 1995a). BPIP provides parameters that are used by the Plume Rise Model Enhancement (PRIME) downwash algorithms in CALPUFF®. Map A-6 in Appendix A shows the locations of the buildings and stacks at the MacLellan site. Map A-7 in Appendix A shows the locations of the buildings and stacks at the Gordon site. All buildings and structures, including tanks, that have potential to cause building downwash effects were included in the BPIP PRIME model. The dimensions of the buildings and structures considered in the dispersion model for Gordon and MacLellan sites are listed in Table E-3.

Table E-3 Locations of Discrete Receptors

Building Description	Building ID	Length (m)	Width (m)	Height (m)
Gordon Site				
Generator	DGEN	15	12	3.5

E.3.8 Deposition Calculation Approach

1. Deposition Parameters

Deposition is comprised of dry and wet removal mechanisms. The dry and wet deposition rates depend on the phase of the compound being deposited (e.g., vapour or particle), and other physical and chemical properties of the compound. For this assessment, deposition is required to predict the following:

- Deposition of dustfall (dry and wet deposition of total suspended particulate (TSP)) to compare against Ontario ambient air quality criteria for dustfall.
- Deposition of metals, PAH (Polycyclic aromatic hydrocarbon) and VOC (Volatile organic compound) as these compounds can have potential adverse effects on environmental health, and on human health. Metals, PAH and VOC concentrations were not modelled directly but were calculated from Total VOC and particulate matter modelling results and estimated emission rates of various metals, PAH and VOC compounds considered. The concentrations of individual compounds were calculated based on the ratio of total emissions to emissions of those compounds specifically.

Table E-4 provides a list of the CAC compound groups associated with the Project, and provides the associated deposition assumptions. Table E-4 also indicates which compounds are vapour or particle phase dominated. All metals are assumed to be associated with the particulate matter phase, except mercury which exist in both vapour and particle phase and is associated with both total VOC and particulate matter. All individual VOCs are associated with the total VOC (vapour phase). PAH species exist in atmosphere in both vapour phase and particle phase and are associated with both total VOC and particulate matter.

Particulate matter (PM) was divided into three size ranges (i.e., 0 to 2.5 µm, 2.5 to 10 µm, and 10 to 30 µm) to account for larger particles being deposited close to the emission sources and smaller particles travelling further downwind prior to being deposited. The deposition values predicted with each size fraction were summed to calculate the total deposition.

For dry deposition, the compound groups are discussed in terms of the deposition options that are available in the CALPUFF model:

- For gaseous VOC and HCN, dry deposition velocity rate is provided as an input using an external file. For these compounds, a constant deposition velocity of 0.5 cm/s (0.005 m/s) was selected (Tables C-23) as per US EPA guidance (US EPA 2005b).
- For vapour mercury, dry deposition is based on a user-specified dry deposition velocity of 2.9 cm/s (0.029 m/s) as per US EPA guidance (US EPA 2005b).
- For PM size based fractions, dry deposition is calculated using the CALPUFF internal particle-phase resistance sub-model. Geometric mass mean diameters and standard deviations for PM size based fractions are listed in Table E-24 at the end of this appendix, and are based on the US EPA guidance document (US EPA 2005b).

The calculation of wet deposition requires wet scavenging coefficients that vary with substance phase (i.e., gas or particle) and form of the precipitation (i.e., liquid (rain) or solid (snow)). The CALPUFF model assumes the scavenging coefficient approach for both gases and particles. The following assumptions are made relative to these parameters:

- For VOC and HCN compounds, the wet scavenging coefficients listed in Table E-24 at the end of this appendix are used; and these are based on the US EPA's Human Health Risk Assessment guidance document (US EPA 2005b).
- For particle size fractions, the scavenging coefficients listed in Table E-24 at the end of this attachment are used; and these are based on US EPA (1995).

Table E-4 Deposition Assumptions

Compound	Percent Vapour	Percent Particle	Dry Deposition
Common Air Contaminants			
SO_2	100	0	Deposition mot modelled
NOx	100	0	Deposition mot modelled
CO	100	0	Deposition mot modelled

Table E-4 Deposition Assumptions

Compound	Percent Vapour	Percent Particle	Dry Deposition
VOC1	100	0	Gas Phase Resistance Model
VOC2 (Surrogate for Gas Phase Mercury)	100	0	Gas Phase Resistance Model
HCN	100	0	Gas Phase Resistance Model
$PM_{2.5}$ (Combustion product)	0	100	Particle Phase Resistance Model
$PM_{2.5}$ to PM_{10} range (Combustion product)	0	100	Particle Phase Resistance Model
PM_{10} to TSP (Combustion product)	0	100	Particle Phase Resistance Model
$PM_{2.5}$ (Fugitive dust)	0	100	Particle Phase Resistance Model
$PM_{2.5}$ to PM_{10} range (Fugitive dust)	0	100	Particle Phase Resistance Model
PM_{10} to TSP (Fugitive dust)	0	100	Particle Phase Resistance Model

E.3.9 Source Parameters

Project emission sources are identified, characterized, and quantified in Appendix C. Depending on the nature of the source types, they can be described as one of the following: point source, Area source, line source or volume source. Differing input parameters are used to represent the source types relevant to the LAA. The locations of all sources are shown in Map A-6 and A-7 in Appendix A.

1. Point Sources

Industrial stacks are treated as point sources. Parameters required for each stack include: stack location, stack base elevation, stack height, stack diameter, stacks gas exit temperature, stack gas exit velocity, and substance emissions rates. There are four stacks associated with processing plant at the MacLellan site and one stack associated with diesel generator at the Gordon site. Parameters to represent these stacks are provided in Table E-5 and further discussed in Appendix C. The industrial stack emission rates are assumed to be constant and continuous.

2. Regional Highways

Traffic emissions from provincial highway 391 (PR391) in the LAA are modelled as line sources and the line sources are represented by multiple volume sources. The US EPA memorandum on haul road emissions (US EPA 2012) and AERMOD guidance document (US EPA 2004) were used to derive appropriate volume source parameters. Highway volume source parameters are provided in Table E-6. Key features include:

- Highway PR391 from Gordon access road to MacLellan access road was selected to represent the main traffic corridor in the LAA. Emissions from this section of highway include general traffic and haul trucks travelling between Gordon and MacLellan site.

- The volume source spacing and the number of individual volume sources to represent each highway segment varies with distance from the mining areas and nearby residential receptors. A smaller spacing (i.e., 50 m) is used to represent highway segments near the Town of Lynn Lake and Black Sturgeon Reserve, and a larger spacing (i.e., 100 m) is used to represent highway segments more distant from the Project, Town of Lynn Lake and Back Sturgeon Reserve.
- The volume source height (VH = 3.5 m) and the top of the plume height (VP = 3.5 m), and the emission release height (RH = VP/2 = 1 .75 m) are related to the dimensions of a typical vehicle. The width of the volume source (PW) is related to the width of the highway and spacing between volume sources (25m - 50 m).
- The turbulence generated by the vehicle wake zone is represented by initial lateral and vertical dimensions referred to a Sy and Sz, respectively. The Sy and Sz values are based on the recommendations provided in the AERMOD model user's guide (US EPA 2004).

This approach mimics an initial well mixed plume associated with vehicle wake zones. The approach, however, does not calculate concentrations for distances less than the volume spacing distance. This disadvantage is not a limitation since locations of interest are further downwind. Emission rates associated with highway sources are discussed and provided in Appendix C Emissions. The emission rates are assumed to be continuous and vary with season (the winter period being November to February, and the summer period being March to October).

3. Volume Sources – Loading/unloading, Bulldozing and Fugitive Emissions from Processing Area Equipment

Emissions from truck loading and unloading, bulldozing and fugitive emissions from processing plant are represented as volume sources. Associated volume source parameters are provided in Table E-7. Table E-8 provides location and base elevation of each sub-volume source. Key features include:

- There are eight Project activities associated with these operations. Each activity is represented by 1 to 4 individual volume sources, depending on the activity.
- The volume source height (VH), the top of plume height (PH), and the emission release height (RH) are related to the dimensions of the dominant piece of equipment. The width of the volume source (PW) is also related to the dimensions of the equipment or the dimensions of the activity.
- The PH and RH are also based on the width and height of the piece of equipment used for the dominant operation.
- Initial Sy and Sz values are calculated based on AERMOD model user's guide (US EPA 2004).

Emission rates associated with the Project sources are discussed and provided in Appendix C.

4. Haul Road Sources

Haul roads are line sources represented as multiple volume sources, similar to highway emission sources. Associated volume source parameters are provided in Table E-9. Key features include:

- Five haul roads are associated with the MacLellan mining area and three haul roads are associated with Gordon mining area. Depending on the length of each haul road, 3 to 44 volume sources represent each haul road, with a volume source spacing of 68 m. Source spacing was calculated based on width of haul road (see Table E-9 footnote).
- The volume source height (VH), the top of plume height (PH), and the emission release height (RH) are related to the dimensions of the associated haul trucks. The width of the volume source (PW) is related to the width of the haul road (RW = 28m) (US EPA 2012).
- The turbulence generated by the vehicle wake zone is represented by initial lateral and vertical dimensions referred to a Sy and Sz, respectively. The Sy and Sz values are based on the recommendations provided in the AERMOD model user's guide (US EPA 2004).

Emission rates associated with the haul roads are discussed and provided in Appendix C. The SO_2, NO_2, CO, VOC and diesel particulate matter emission rates are modelled as continuous emissions and fugitive particulate matter emissions are modelled with seasonal emissions rates (Winter months are November to April and summer months are May to October).

5. **Access Road Sources**

Access roads are line sources represented as multiple volume sources, similar to highway emission sources. Associated volume source parameters are provided in Table E-10. Key features include:

- Three access roads are associated with the MacLellan mining area and two access roads are associated with Gordon mining area. Depending on the length of each access road, 75 to 129 volume sources represent each access road, with a volume source spacing of 50 or 100 m.
- The volume source spacing and the number if individual volume sources to represent each access road varies with distance from the mining areas. A smaller spacing (i.e., 50 m) is used to represent access road segments near the mining areas, and a larger spacing (i.e., 100 m) is used to represent access road segments more distant from the mining areas.
- The volume source height (VH), the top of plume height (PH), and the emission release height (RH) are related to the dimensions of the associated haul trucks. The width of the volume source (PW) is related to the width of the access road (RW = 25m) (US EPA 2012).
- The turbulence generated by the vehicle wake zone is represented by initial lateral and vertical dimensions referred to a Sy and Sz, respectively. The Sy and Sz values are based on the recommendations provided in the AERMOD model user's guide (US EPA 2004).

Emission rates associated with the access roads are discussed and provided in Appendix C. The SO_2, NO_2, CO, VOC and diesel particulate matter emission rates are modelled as continuous emissions and fugitive particulate matter emissions are modelled with seasonal emissions rates (Winter months are November to April and summer months are May to October).

6. Stockpiles

The mining operations will require overburden, waste rock, low grade ore, and topsoil stockpiles. Wind erosion emissions from the stockpiles are represented by area sources. Table E-11 shows area source parameters used for the stockpiles and Table E-12 provides locations of the area sources. The fugitive emission rates for each hour depend on the wind speed for that hour. The wind speed profile and scaling factors used to model wind erosion emissions from stockpiles are provided in Table E-13. Fugitive emissions from stockpiles only occur if wind speed is above 16.4 m/s. Emission rates associated with the stockpiles are further discussed and provided in Appendix C.

7. Tailing Management Facility (TMF) and General Operations Area

Tailings management facility pond is a source of HCN emissions through evaporation and TMF banks are source of fugitive dust emissions by wind erosion. Emissions from equipment operating in area around the processing plant at MacLellan site and around operations buildings at Gordon site are modelled as area sources. Table E-14 shows area source parameters used for the TMF and general operations areas and Table E-15 provides locations of the area sources. The wind erosion fugitive emission rates from TMF banks for each hour depend on the wind speed for that hour. The wind profile and scaling factors used to model wind erosion emissions from tailing management facility are provided in Table E-16. Fugitive particulate emissions from TMF banks only occur if wind speed is above 7.2 m/s. More detailed descriptions of emissions are provided in Appendix C

8. Open Mining Pits

The main activities within the open pits that result in emissions are haul roads within the pit area, loading and bulldozing, and open pit blasting. These emissions sources are modelled as area sources. Table E-17 shows the area source parameters used for the open pit sources and Table E-18 provides locations of open pit mining areas.

- The vehicle height (VH), the top of plume height (PH), and the emission release height (RH) are related to the dimensions of the associated haul trucks.
- Release height of blasting emissions is based on assumed plume height of 10 m.
- Blasting will occur between 7 pm and 8 pm on Sunday, Monday and Thursday of each week.
- Open pit retention calculation is used to adjust emission rate of fugitive emissions from the open pit (detail below).

Emission rates associated with the open pit haul roads are discussed and provided in Appendix C. The SO_2, NO_2, CO, VOC and diesel particulate matter emission rates are modelled as continuous emissions and fugitive particulate matter emissions are modelled with seasonal emissions rates (Winter months are November to April and summer months are May to October). Emissions from loading and bulldozing are modelled as continuous sources.

Since CALPUFF® does not have an algorithm to model open pit sources, the open pits were modelled as surface area sources with reduced PM emissions to account for the fraction of PM emissions retained in the open pit due to its depth, known as “pit retention”. Pit retention is the term used to describe the tendency for PM emissions released inside an open mine pit to remain inside the pit. The fraction of PM emissions that is retained in the open pit depends on the depth of the pit and the particle size (Winges 1986). A 50% pit retention for TSP emissions and 5% pit retention for PM_{10} emissions was applied based on recommendation in the Australian Emission Manual for Mining (Australian Government 2012). The fraction of $PM_{2.5}$ emissions retained in the open pits was estimated based on the original Winges equation (Winges 1981) assuming a pit depth of 150 m for Gordon site (Year 2) and 245 m for MacLallan site (Year 7). The calculated pit retention fraction of $PM_{2.5}$ emissions is 1% for the open pit at Gordon site and 2% for the open pit at MacLellan site. Details on the pit retention fractions used for PM emissions from the open pits at Gordon and MacLellan sites are provided in Appendix C. All emission sources in the open pit are modelled as surface area sources representing the open pit, including drilling and blasting emissions, diesel exhaust emissions from mining off-road equipment operating in the pit and fugitive dust emissions from mining off-road equipment movement, bulldozing, grading and truck loading.

Table E-5 Point Source Parameters

Model Source ID	Source Description	Operations	Source Parameters						
			UTM Easting	UTM Northing	Base Elevation	Stack Height	Stack Diameter	Exit Temperature	Exit Velocity

NOTES:

Location based on UTM Zone 14, NAD 83

[a] Vehicle Height (VH) = 5.67 m (CAT 785D mining truck). Top of plume Height (PH) = 1.7 x VH = 9.64 m. Release Height (RH) = 1/2 x PH = 4.82 m. Road Width (RW) = 25 m for haul roads. Plume Width (PW) = RW + 6 m. PW = 34 m for haul roads. Volume source separation distance = 68 m (double of plume width) US EPA (2012).

[b] Vehicle Height (VH) = 3.50 m (Peterbilt 367 mining truck). Top of plume Height (PH) = 1.7 x VH = 5.95 m. Release Height (RH) = 1/2 x PH = 2.98 m. Road Width (RW) = 25 m for haul roads. Plume Width (PW) = RW + 6 m. PW = 34 m for haul roads. Volume source separation distance = 68 m (double of plume width) US EPA (2012).

[c] Initial Vertical Dimension (Sz) = PH/2.15

Initial Vertical Dimension (Sy) = PW/4.3

UTM easting and northing is provided for the first sub-volume source.

ML – MacLellan mining area

GD – Gordon mining area

Table E-10 Source Parameters for Access Roads

Source ID	Unit Description	Mine Area	Temporal Variation	Source Parameters										
				UTM Easting	UTM Northing	Base Elevation	PH	PW	RH	Inter-Volume Distance	Sy	Sz	Length of Road	Number of Sub-Volumes
				m E	m N	m	m	m	m	m	m	m	m	#
AR_WC_M [a]	Access Road to Worker's Camp at Maclellan Site	ML	Continuous/ Seasonal	377884	6304355	348	3.40	25	1.70	50	23.3	1.58	5594	113
AR_EM_M [b]	Access Road to Explosive Magazine at Maclellan Site	ML	Continuous/ Seasonal	377884	6304355	348	5.95	25	2.98	50	23.3	2.77	6400	129
ARO_M [b]	Access Road to Mill at Maclellan Site	ML	Continuous/ Seasonal	377884	6304355	348	5.95	25	2.98	50	23.3	2.77	5250	106
AR1_G [b]	Access Road Segment 1 at Gordon Site	GD	Continuous/ Seasonal	412358	6307342	321	5.95	25	2.98	50	23.3	2.77	3689	75
AR2_G [b]	Access Road Segment 2 at Gordon Site	GD	Continuous/ Seasonal	411647	6303676	300	5.95	50	2.98	100	46.5	2.77	11097	112

NOTES:

Location based on UTM Zone 14, NAD 83

[a] Vehicle Height (VH) = 3.50 m (Peterbilt 367 mining truck). Top of plume Height (PH) = 1.7 x VH = 5.95 m. Release Height (RH) = 1/2 x PH = 2.98 m. Plume Width = half of intervolume distance. Volume source separation distance = 50 -100 m (double of plume width) US EPA (2012).

[b] Vehicle Height (VH) = 3.50 m (Pick-up truck). Top of plume Height (PH) = 1.7 x VH = 3.40 m. Release Height (RH) = 1/2 x PH = 1.70 m. Plume Width = half of intervolume distance of 50m. Volume source separation distance = 50 m (double of plume width) US EPA (2012).

[c] Initial Vertical Dimension (Sz) = PH/2.15
Initial Lateral Dimension (Sy) = Inter-volume distance/2.15

UTM easting and northing is provided for the first sub-volume source.

ML – MacLellan mining area

GD – Gordon mining area

Table E-11 Source Parameters for Stockpile Area Sources

Model ID	Source Description	Mine Area	Temporal Variation	Source Parameters			
				Release Height	Initial Vertical Dimension	Area	Number of Sub-Areas
				m	m	m²	#
WE_OVB_M	Overburden Stockpile Wind Erosion at MacLellan site	ML	Variable, Only When Wind Speed is > 16.4 m/s	20.0	1	151756	5
WE_WR_M	Waste Rock Stockpile Wind Erosion at MacLellan site	ML	Variable, Only When Wind Speed is > 16.4 m/s	30.0	1	2622566	11

E.3.10 Interpretation of Predictions

1. Hourly and Daily Emission Rates

For this assessment, each emission source was modelled separately with CALPUFF model using 1 g/s emission rate. CALUFF postprocessor CALSUM was then used to combine model results from all emission sources by scaling the actual emission rate of each source for each contaminant.

MacLellan and Gordon mining operations emissions are calculated for both hourly and daily emission rates, as discussed in Appendix C. CALSUM was used to combine all emission source separately for hourly and daily emissions rate scenarios. Model results based on hourly emission rates were used to determine 1-hour and 8-hour average predicted concentrations. Model results based on daily emission rates were used to determine 24-hour and annual average predicted concentrations.

2. Comparison to Ambient Air Quality Objectives

The Manitoba AQMG does not specify any methodology on how to compare predicted concentrations against the ambient air quality objectives. In absence of any direction on interpretation of results, the Ontario air dispersion modelling guideline (MOECC 2016) methodology was used.

The Ontario guideline states that in modelling applications using regional or local meteorological data sets, certain extreme, rare and transient meteorological conditions may be present in the data sets that may be considered outliers. For shorter averaging periods, such as 1-hour concentrations, the meteorological conditions for the eight hours with the highest 1-hour average predicted concentrations in each single meteorological year are considered as anomalies and may be discarded. The highest concentration after elimination of these forty meteorological anomalies over the five-year period from the modelling results is compared against the ambient air quality criteria.

For assessment of 24-hour average concentrations, the highest 24-hour average predicted concentration in each single meteorological year may be discarded. For annual concentrations, the highest annual concentrations in the 5-year period will be considered, without removal of any meteorological anomalies.

3. Contour Concentration and Deposition Plots

Ambient concentration and deposition predictions are displayed as contour plots superimposed over base maps for the local assessment area (LAA). The concentration contour plots are based on the maximum values from the five-year simulation period. In preparing these contour plots, a grid spacing of 200 m was adopted for the LAA contour plots. This may result in some “smoothing” of the contours. However, tabular results are also provided which precisely represent the results at the discrete receptors based on the emissions estimates and model outputs with no smoothing or other manipulation.

E.4 SUMMARY AND CONCLUSIONS

The CALPUFF dispersion model (most recent Version 7.2.1, Level 150618) was selected as the primary air quality assessment tool to predict ambient concentrations and deposition for the air quality assessment. The following are adopted for the application of the model:

- 16,343 gridded and sensitive receptor points to assess criteria air contaminant (CAC), VOC, PAH and metal concentrations, and TSP and metal deposition for the 28 km by 50 km LAA.
- Five years of meteorological data for the period January 2012 to December 2016 to represent the wide range of weather conditions that could occur. The CALMET model (see Appendix D) was used to provide the meteorological data for the CALPUFF model.
- The OLM was selected to estimate ambient NO_2 concentrations from the predicted NO_X values.
- The CALPUFF model was applied to MacLellan and Gordon emissions using the source and emission inventory information described in Appendix C.

The approach and input parameters were selected to determine air quality changes due to the Project.

E.5 CALPUFF MODEL OPTIONS

For the purposes of organization, the CALPUFF control file defines 20 input groups as identified in Table E-19. The input parameters for the CALPUFF control file used in this modelling assessment are provided in Tables E-20 to E-27. The Manitoba and Ontario AQMG does not provide guidance on assumptions and switches to be used. Alberta and British Columbia AQMG were used to set up CALPUFF model input file. In absence of specific guidance, the default values are assumed to be those defined in the CALPUFF user manual (Scire et al. 2000). These non-default values are highlighted by orange shading in the following tables. The default values and the values adopted for this updated assessment are identified in the tables.

Table E-19 Input Groups in the CALPUFF Control File

Input Group	Description	Applicable to Project?
0	Input and output file names	Yes
1	General run control parameters	Yes
2	Technical options	Yes
3	Species list	Yes
4	Map projection and grid control parameters	Yes
5	Output options	Yes
6	Sub grid scale complex terrain inputs	No
7	Dry deposition parameters for gases	Yes
8	Dry deposition parameters for particles	Yes
9	Miscellaneous dry deposition for parameters	Yes
10	Wet deposition parameters	Yes
11	Chemistry parameters	No
12	Misc. dispersion and computational parameters	Yes
13	Point source parameters	Yes
14	Area source parameters	Yes
15	Line source parameters	No
16	Volume source parameters	Yes
17	Flare source control parameters	No
18	Road emissions parameters	No
19	Emission rate scale-factor tables	Yes

Table E-20 CALPUFF Model Options Groups 1 and 2

Input Group 1: General Run Control Parameters

Parameter	Default	Project	Comments
METRUN	0	0	All model periods in met file(s) will be run
IBYR	-	2012	Starting year
IBMO	-	1	Starting month
IBDY	-	1	Starting day
IBHR	-	0	Starting hour
IEYR	-	2016	Ending year
IEMO	-	1	Ending month
IEDY	-	1	Ending day
IEHR	-	0	Ending hour
ABTZ		UTC-0600	Base time zone (6 = CST)
NSPEC	5	12	Number of chemical species
NSE	3	12	Number of chemical species to be emitted
ITEST	2	2	Program is executed after SETUP phase
MRESTART	0	0	Do not read or write a restart file during run
NRESPD	0	0	File updated every 24 periods
METFM	1	1	CALMET binary file (CALMET.MET)
MPRFFM	1	1	Meteorological Profile Data Format
AVET	60	60	Averaging time in minutes
PGTIME	60	60	PG Averaging time in minutes
IOUTU	1	1	Output units for binary concentration and flux files written in Dataset v2.2 or later formats. 1 = mass - g/m^3 (concentration) or $g/m^2/s$ (deposition)

Input Group 2: Technical Options

Parameter	Default	Project	Comments
MGAUSS	1	1	Gaussian distribution used in near field
MCTADJ	3	3	Partial plume path terrain adjustment
MCTSG	0	0	Scale-scale complex terrain not modelled
MSLUG	0	0	Near-field puffs not modelled as elongated
MTRANS	1	1	Transitional plume rise modelled
MTIP	1	1	Stack tip downwash used

Table E-20 CALPUFF Model Options Groups 1 and 2

Input Group 2: Technical Options (cont'd)

Parameter	Default	Project	Comments
MRISE	1	1	Method used to compute plume rise for point sources not subject to building downwash 1 = Briggs plume rise
MTIP_FL	0	0	No stack-tip downwash for flare sources
MRISE_FL	2	2	Plume rise module for flare sources; 2=Numerical plume rise
MBDW	1	2	PRIME Method is used to simulate building downwash as per the BC and Alberta AQMG
MSHEAR	0	0	Vertical wind shear is not modelled
MSPLIT	0	0	Puff splitting not used as per the AQMG
MCHEM	1	0	Chemical Transformation not modelled
MAQCHEM	0	0	Aqueous phase transformation not modelled
MLWC	1	1	Liquid Water Content flag (Used only if MAQCHEM = 1)
MWET	1	1	Wet removal modelled
MDRY	1	1	Dry deposition modelled
MTILT	0	0	Gravitational settling (plume tilt) modelled for fugitive dust
MDISP	3	2	Dispersion coefficients from internally calculated sigma v, sigma w using micrometeorological variables (u*, w*, L, etc.) as per the AQMG 9 (as per the BC and Alberta AQMG)
MTURBVW	3	3	Use both σ_v and σ_w from PROFILE.DAT to compute σ_y and σ_z (n/a)
MDISP2	3	3	PG dispersion coefficients for rural areas (computed using ISCST3 approximation) and MP coefficients in urban areas when measured turbulence data is missing
MTAULY	0	0	Draxler default 617.284 (s)
MTAUADV	0	0	No turbulence advection
MCTURB	1	1	Standard CALPUFF subroutines
MROUGH	0	0	PG σ_y and σ_z is not adjusted for roughness
MPARTL	1	1	Partial plume penetration of elevated inversion
MPARTLBA	1	1	Partial plume penetration of elevated inversion modelled for the buoyant area sources (as per the BC and Alberta AQMG)
MTINV	0	0	Strength of temperature inversion computed from default gradients
MPDF	0	1	The probability density function (PDF) to be used for dispersion under convective conditions as per the BC and Alberta AQMG

Table E-20 CALPUFF Model Options Groups 1 and 2

Input Group 2: Technical Options (cont'd)

Parameter	Default	Project	Comments
MSGTIBL	0	0	Sub-grid TIBL module not used for shoreline
MBCON	0	0	Boundary concentration conditions not modelled
MSOURCE	0	0	Individual source contributions not saved
MFOG	0	0	Do not configure for FOG model output
MREG	1	0	Do not test options specified to see if they conform to regulatory values as per the AQMG

Table E-21 CALPUFF Model Options Groups 3 and 4

Input Group 3: Species List-Chemistry Options

CSPEC	Modelled[1]	Emitted[2]	Dry Deposition[3]	Output Group Number
SO_2	1	1	0	0
NOx	1	1	0	0
CO	1	1	0	0
VOC1	1	1	3	0
VOC2	1	1	3	0
HCN	1	1	3	0
$PM_{2.5}$ (Combustion product)	1	1	2	0
$PM_{2.5}$ to PM_{10} range (Combustion product)	1	1	2	0
PM_{10} to TSP (Combustion product)	1	1	2	0
$PM_{2.5}$ (Fugitive dust)	1	1	2	0
$PM_{2.5}$ to PM_{10} range (Fugitive dust)	1	1	2	0
PM_{10} to TSP (Fugitive dust)	1	1	2	0

NOTES:

[1] 0=no, 1=yes

[2] 0=no, 1=yes

[3] 0=none, 1=computed-gas, 2=computed particle, 3=user-specified

VOC was modelled twice – VOC1 was used for simulating PAH concentration and deposition and VOC2 for simulating mercury (gaseous form) concentration and deposition because PAH and gaseous mercury have different dry and wet deposition parameters.

Input Group 4: Map Projection and Grid Control Parameters

Parameter	Default	Project	Comments
PMAP	UTM	UTM	Universal Transverse Mercator
FEAST	0	0	False Easting (km) at the projection origin
FNORTH	0	0	False Northing (km) at the projection origin
IUTMZN	-	14	UTM zone
UTMHEM	N	N	Northern Hemisphere for UTM projection
DATUM	WGS-84	NAR-C	NAR-C is applicable for this assessment. WGS-84 is just the datum for TRC demo case along with the CALPUFF release.
NX	-	140	Number of X grid cells in meteorological grid
NY		96	Number of Y grid cells in meteorological grid
NZ	No default	12	Vertical grid definition: Number of vertical layers as per the AEP Model Guideline.

Table E-22 CALPUFF Model Options Groups 3 and 4

Input Group 4: Map Projection and Grid Control Parameters (cont'd)

DGRIDKM	-	0.5	Grid spacing (km) to match CALMET (see Appendix C)
ZFACE	No default	0, 20, 40, 80, 120, 280, 520, 880, 1320, 1820, 2380, 3000 and 4000	Vertical grid definition: Cell face heights (m)
XORIGKM	-	361.775	Reference X coordinate for SW corner of grid cell (1,1) of meteorological grid (km)
YORIGKM	-	6278.500	Reference Y coordinate for SW corner of grid cell (1,1) of meteorological grid (km)
IBCOMP	-	1	X index of lower left corner of the computational grid
JBCOMP	-	1	Y index of lower left corner of the computational grids
IECOMP	-	140	X index of the upper right corner of the computational grid
JECOMP	-	96	Y index of the upper right corner of the computational grid
LSAMP	T	F	Sampling grid is not used
IBSAMP	-	1	X index of lower left corner of the sampling grid
JBSAMP	-	1	Y index of lower left corner of the sampling grid
IESAMP	-	140	X index of upper right corner of the sampling grid
JESAMP	-	96	Y index of upper right corner of the sampling grid
MESHDN	1	1	Nesting factor of the sampling grid

Table E-23 CALPUFF Model Option Group 5

Input Group 5: Output Option

Parameter	Default	Project	Comments
ICON	1	1	Output file CONC.DAT containing concentrations is created
IDRY	1	1	Output file DFLX.DAT containing dry fluxes is created
IWET	1	1	Output file WFLX.DAT containing wet fluxes is created
IT2D	0	0	2D Temperature
IRHO	0	0	Density
IVIS	1	0	Output file containing relative humidity data is not created
LCOMPRS	T	T	Do not perform data compression in output file
IQAPLOT	1	1	Create a standard series of output files (e.g., locations of sources, receptors, grids ...) suitable for plotting
IMFLX	0	0	Do not calculate mass fluxes across specific boundaries
IPFTRAK	0	0	Puff locations and properties reported to PFTRAK.DAT file for postprocessing
IMBAL	0	0	Mass balances for each species are not reported hourly
INRISE	0	0	Create a file with plume properties for each rise increment, for each model timestep
ICPRT	0	0	Do not print concentration fields to the output list file
IDPRT	0	0	Do not print dry flux fields to the output list file
IWPRT	0	0	Do not print wet flux fields to the output list file
ICFRQ	1	72	Concentration fields are printed to output list file every 24-hour
IDFRQ	1	72	Dry flux fields are printed to output list file every 24-hour
IWFRQ	1	72	Wet flux fields are printed to output list file every 24-hour
IPRTU	1	3	Units for line printer output are in µg/m^3 for concentration and µg/m^2/s for deposition
IMESG	2	2	Messages tracking the progress of run are written on screen
LDEBUG	F	F	Logical value for debug output
IPFDEB	1	1	First puff to track
NPFDEB	1	1	Number of puffs to track
NN1	1	1	Meteorological period to start output
NN2	10	10	Meteorological period to end output

Table E-24 CALPUFF Model Option Groups 6 and 7

Input Group 6: Sub-Grid Scale Complex Terrain Inputs

Parameter	Default	Project	Comments
NHILL	0	0	Number of terrain features
NCTREC	0	0	Number of special complex terrain receptors
MHILL	-	2	Hill data created by OPTHILL & input below in Subgroup (6b); Receptor data in Subgroup (6c)
XHILL2M	1	1	Conversion factor for changing horizontal dimensions to metres
ZHILL2M	1	1	Conversion factor for changing vertical dimensions to metres
XCTDMKM	-	0	X origin of CTDM system relative to CALPUFF coordinate system (km)
YCTDMKM	-	0	Y origin of CTDM system relative to CALPUFF coordinate system (km)

Input Group 7: Dry Deposition Parameters for Gases [a]

Species	Dry deposition Velocity (m/s)	Comments
VOC1	0.005	PAH dry deposition velocity
VOC2	0.029	Dry deposition of gaseous mercury
HCN	0.005	-

NOTE:
[a] Dry deposition velocities were provided as external file to CALPUFF model input (VD.dat)

Table E-25 CALPUFF Model Option Groups 8, 9, 10, and 11

Input Group 8: Dry Deposition Parameters for Particles

Species	Default	Project	Comments
$PM_{2.5}$ (Combustion product)	-	1.6	Geometric mass mean diameter of PM [µm]
$PM_{2.5}$ (Combustion product)	-	0.0	Geometric standard deviation of PM [µm]
$PM_{2.5}$ to PM_{10} range (Combustion product)	-	6.9	Geometric mass mean diameter of PM [µm]
$PM_{2.5}$ to PM_{10} range (Combustion product)	-	0.0	Geometric standard deviation of PM [µm]
PM_{10} to TSP (Combustion product)	-	21.5	Geometric mass mean diameter of PM [µm]
PM_{10} to TSP (Combustion product)	-	0.0	Geometric standard deviation of PM [µm]
$PM_{2.5}$ (Fugitive dust)	-	1.6	Geometric mass mean diameter of PM [µm]
$PM_{2.5}$ (Fugitive dust)	-	0.0	Geometric standard deviation of PM [µm]
$PM_{2.5}$ to PM_{10} range (Fugitive dust)	-	6.9	Geometric mass mean diameter of PM [µm]
$PM_{2.5}$ to PM_{10} range (Fugitive dust)	-	0.0	Geometric standard deviation of PM [µm]
PM_{10} to TSP (Fugitive dust)	-	21.5	Geometric mass mean diameter of PM [µm]
PM_{10} to TSP (Fugitive dust)	-	0.0	Geometric standard deviation of PM [µm]
NOTES: Geometric mass mean diameter and geometric standard deviation pf different size fractions are derived from US EPA (2005b)			

Input Group 9: Miscellaneous Dry Deposition Parameters

Parameters	Default	Project	Comments
RCUTR	30	30	Reference cuticle resistance (s/cm)
RGR	10	10	Reference ground resistance (s/cm)
REACTR	8	8	Reference pollutant reactivity
NINT	9	9	Number of particle size intervals for effective particle deposition velocity
IVEG	1	1	Vegetation in non-irrigated areas is active and unstressed

Table E-26 CALPUFF Model Option Groups 8, 9, 10, and 11

Input Group 10: Wet Deposition Parameters

Species	Default	Project	Comments
VOC1	-	1.7E-04	Scavenging coefficient for liquid precipitation [s^{-1}]
	-	6.0E-05	Scavenging coefficient for frozen precipitation [s^{-1}]
VOC2	-	2.0E-04	Scavenging coefficient for liquid precipitation [s^{-1}]
	-	7.0E-05	Scavenging coefficient for frozen precipitation [s^{-1}]
HCN	-	1.7E-04	Scavenging coefficient for liquid precipitation [s^{-1}]
	-	6.0E-05	Scavenging coefficient for frozen precipitation [s^{-1}]
$PM_{2.5}$ (Combustion product)	-	6.0E-05	Scavenging coefficient for liquid precipitation [s^{-1}]
	-	2.0E-05	Scavenging coefficient for frozen precipitation [s^{-1}]
$PM_{2.5}$ to PM_{10} range (Combustion product)	-	4.2E-04	Scavenging coefficient for liquid precipitation [s^{-1}]
	-	1.4E-04	Scavenging coefficient for frozen precipitation [s^{-1}]
PM_{10} to TSP (Combustion product)	-	6.6E-04	Scavenging coefficient for liquid precipitation [s^{-1}]
	-	2.2E-04	Scavenging coefficient for frozen precipitation [s^{-1}]
$PM_{2.5}$ (Fugitive dust)	-	6.0E-05	Scavenging coefficient for liquid precipitation [s^{-1}]
	-	2.0E-05	Scavenging coefficient for frozen precipitation [s^{-1}]
$PM_{2.5}$ to PM_{10} range (Fugitive dust)	-	4.2E-04	Scavenging coefficient for liquid precipitation [s^{-1}]
	-	1.4E-04	Scavenging coefficient for frozen precipitation [s^{-1}]
PM_{10} to TSP (Fugitive dust)	-	6.6E-04	Scavenging coefficient for liquid precipitation [s^{-1}]
	-	2.2E-04	Scavenging coefficient for frozen precipitation [s^{-1}]
NOTES: VOC and PM size fractions scavenging coefficients are from US EPA (1995)			

Input Group 11: Chemistry Parameters

NA	Chemical Transformation not modelled

Table E-27 CALPUFF Model Option Group 12

Input Group 12: Diffusion/Computational Parameters

Parameters	Default	Project	Comments
SYTDEP	550	550	Horizontal size of a puff in metres beyond which the time dependent dispersion equation of Heffter (1965) is used
MHFTSZ	0	0	Do not use Heffter formulas for sigma z
JSUP	5	5	Stability class used to determine dispersion rates for puffs above boundary layer
CONK1	0.01	0.01	Vertical dispersion constant for stable conditions
CONK2	0.1	0.1	Vertical dispersion constant for neutral/stable conditions
TBD	0.5	0.5	Use ISC transition point for determining the transition point between the Schulman-Scire (Schulman et al., 1998) to Huber-Snyder Building Downwash scheme
ISIGMAV	1	1	Sigma-v is read for lateral turbulence data
IMIXCTDM	0	0	Predicted mixing heights are used
XMXLEN	1	1	Maximum length of emitted slug in meteorological grid units
XSAMLEN	1	1	Maximum travel distance of slug or puff in meteorological grid units during one sampling unit
MXNEW	99	99	Maximum number of puffs or slugs released from one source during one time step
MXSAM	99	99	Maximum number of sampling steps during one time step for a puff or slug
NCOUNT	2	2	Number of iterations used when computing the transport wind for a sampling step that includes transitional plume rise
SYMIN	1	1	Minimum sigma y in metres for a new puff or slug
SZMIN	1	1	Minimum sigma z in metres for a new puff or slug
SZCAP_M	5.0E06	5.0E06	Maximum sigma z in metres to avoid numerical problem in calculating time or distance

Stability Class	Parameter

Appendix F GREENHOUSE GAS EMISSIONS FOR CONSTRUCTION AND OPERATION

F.1 INTRODUCTION

This appendix includes information on greenhouse gases (GHGs) generated by the Lynn Lake Gold Project (the Project). There are six main greenhouse gases potentially associated with the Project including carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs) and sulphur hexachloride (SF_6) out of which only CO_2, CH_4, and N_2O will be emitted by the Project.

The GHG Protocol classifies the GHG emissions into the three following categories (WRI 2013):

Direct GHG emissions (Scope 1): Emissions released from sources that are owned or controlled by the Project.

Indirect GHG emissions (Scope 2): Emissions from the purchased electricity generated offsite by sources owned or controlled by another entity.

Other Indirect GHG emissions (Scope 3): Emissions from other indirect activities (except electricity) generated offsite by that are owned or controlled by another entity. Upstream sources such as production and processing of purchased materials and transportation are assumed to be negligible compared to direct GHG emissions and would not be greatly influenced by the Project. Therefore, Scope 3 is not evaluated for this assessment and it is an optional reporting category as per GHG Protocol (WRI 2013).

Emissions from each of these specific GHGs have been estimated and multiplied by their 100-year global warming potential (GWP) so they can be reported as carbon dioxide equivalents (CO_2e). CO_2e is the standardized way to report GHGs.

The GWP (IPCC 2012) of these GHGs applied in this assessment are as follows:

- CO_2 = 1.0
- CH_4 = 25
- N_2O = 298

On this basis, carbon dioxide equivalents for the Project are calculated as:

CO_2e = (mass CO_2 x 1.0) + (mass CH_4 x 25) + (mass N_2O x 298)

This appendix includes the following GHG inventory related information:

- details on the scope of activities during each Project phase (Construction and Operation)

- description of methods used to assess potential effects of the project on GHG emissions during construction and operation
- construction and operation GHG emissions summaries
- comparison to provincial and national GHG emissions

F.2 GHG POLLUTION PRICING ACT

The Government of Canada passed the *Greenhouse Gas Pollution Pricing Act* on June 21, 2018 implementing a federal carbon pricing system for provinces and territories which do not have a carbon pricing system or have a system that does not meet the federal benchmark requirements (Government of Canada, 2020). This federal pricing system has two key parts:

- a charge on fossil fuels which will be administered by Canada Revenue Agency (CRA), and
- output-based pricing system (OBPS) for industrial facilities which will be administered by Environment and Climate Change Canada (ECCC).

The charge on the fossil fuel and OBPS will be implemented starting April 1, 2019 with future increases effective as of April each following year and January 1, 2019 respectively. The Project purchases and consumes diesel fuel during the construction and operation phase hence the mine operator will be paying these charges, as required by the *Greenhouse Gas Pollution Pricing Act*. The charge for fossil fuel increases each year based on the carbon pollution pricing. The fuel charges for diesel in Manitoba in 2019 is 0.0537 $/litre, 2020 is 0.0805 $/litre, 2021 is 0.1073 $/litre, and 2022 is 0.1341 $/litre. The objective of applying the fuel charge at higher rates over time is to encourage reductions in GHG emissions and support clean growth, while keeping costs low for Canadians and Canadian businesses.

F.3 PROJECT PHASES

F.3.1 CONSTRUCTION PHASE

There are two years in the Project construction phase (defined as Year -2 and Year -1 in reference to the overall Project timeline). Project construction starts in year -2 with works such as road construction, mine platforms, processing plant construction, tailings management facility (TMF) construction, and preproduction. The worst-case year of construction was selected based on the most overlapping construction activities, the largest number of construction equipment units and the highest construction material movement. The 12-month period from Q2 Year -2 to Q1 Year -1 (i.e., Q2 2021 to Q1 2022) was determined as the worst-case year of construction for both the Gordon and MacLellan sites. The GHG emissions from this worst-case year were estimated for the construction phase and are described in this report.

The sources of direct (Scope 1) GHG emissions during construction are:

- Off-Road equipment
  - Diesel combustion in off-road equipment (CO_2, CH_4, N_2O)
- On-Road Equipment
- Diesel combustion in on-road equipment (CO_2, CH_4, N_2O)Blasting
  - Explosives (CO_2)
- Land Clearing
  - Salvage, uprooting and burning (CO_2e)

F.3.2 OPERATION PHASE

The operation GHG emissions have been assessed by quantifying GHG emissions for a “worst case” year of operation at both Gordon and MacLellan. The worst-case years of operation coincide with the peak production rate (for overburden, mine rock and ore) that will result in the highest GHG emissions. The worst-case year for operation was selected based on the highest overburden, mine rock and ore production rate, the largest number of mining equipment units and the highest movements of overburden, mine rock and ore measured in tonnes. Year 2 was determined to be the worst-case year of operation for the Gordon site and Year 7 the worst-case year of operation for the MacLellan site. The GHG emissions from the worst-case year of operation at the Gordon site (Year 2) and the MacLellan site (Year 7) were estimated and are described in this report .

The sources of direct (Scope 1) GHG emissions during operation are:

- Off-Road equipment
  - Diesel combustion in off-road equipment (CO_2, CH_4, N_2O)
- On-Road Equipment
  - Diesel combustion in on-road equipment (CO_2, CH_4, N_2O)
- Blasting
  - Explosives (CO_2)

The sources of indirect (Scope 2) GHG emissions during operation are:

- Electricity
  - Electricity Consumption (CO_2e)

NOTE: The GHGs emission from decommissioning of the Project have not been estimated as these activities are expected to be substantially lower GHG emissions than the annual GHG emissions from construction or operation phases.

F.4 METHODS

F.4.1 DIRECT GHG EMISSIONS

Direct GHG emissions (Scope 1) are emissions released from sources that are owned or controlled by the Project (WRI 2013). These emissions sources include the off-road and on-road equipment, blasting and land clearing.

F.4.1.1 Off-Road Combustion Equipment

GHG emissions from off-road equipment are from hydraulic shovels, loaders, articulated trucks, graders, dozers, excavators, forklifts, backhoes, cranes, pumps, drills, generators, crushers, air compressors, pressure washers, light towers, etc. The list of off-road equipment and their operating hours for the mine preproduction and operation were provided by the mine planning subcontractor, Q'Pit Inc.(Q'Pit, Q'Pit 2019) whereas the list of off-road equipment and their operating hours used for the processing plant and tailings management facility constructions were provided by the mine planning contractor, Ausenco (Ausenco 2019a and Ausenco 2019b). Off-road diesel exhaust GHG emissions were estimated based on the National Inventory Report (NIR) off-road diesel combustion emission factors (Environment and Climate Change Canada (ECCC) 2019a), fuel consumption rate and operating hours. Equation F-1 was used to determine the emission rates. The emission factors from NIR are presented in Table F-1. The fuel consumption was estimated using Equation F-2.

The GHG emissions from off-road equipment are calculated using the following equation:

$$\begin{aligned} Emission\ (tonnes/year) &= Number\ of\ Units \times Fuel\ Consumption\ Rate\left(\frac{L}{hour}\right) \\ &\times Emission\ Factor\left(\frac{g}{L}\right) \times Annual\ Operating\ hours\left(\frac{hour}{year}\right) \\ &\times Load\ Factor\ (\%) \times Unit\ Conversion\left(\frac{tonnes}{10^6 g}\right) \end{aligned}$$

Equation F-1

where

Emission	-	Annual emission rate (tonnes/year or t/y)
Number of Units	-	Number of each type of equipment
Fuel Consumption Rate	-	Hourly fuel consumption of equipment (L/hour)
Emission Factor	-	off-road diesel combustion emission factor (ECCC, 2019a)

Operating hours	-	Equipment operating hours per year (hour/year)
Load Factor	-	Equipment load factor (%) by equipment type based on US EPA NONROAD model documentation (US EPA 2010a). Defined as the fraction of actual engine output relative to maximum rated power, taking into account that engines are operating somewhere between idle speed and full power.

Table F-1 Off-Road Diesel Combustion GHG Emission Factors

Equipment Description	CO_2	CH_4	N_2O
	(g/L)		
Off-road Diesel Equipment	2,681	0.073	0.227

NOTES:
[a] Based on ECCC emission factors provided in Table A6-13 of the National Inventory Report (ECCC 2019a).

The fuel consumption for each off-road equipment is calculated using the following equation:

$$Fuel\ Consumption\ (L/hour) = Engine\ Power\ (hp) \times BSFC\ \left(\frac{lb\ diesel}{hp\ hr}\right) \times Unit\ Conversion\ \left(\frac{kg}{2.205\ lb}\right) \times \frac{1}{Diesel\ Density\ (0.85\ \frac{kg}{L})}$$

Equation F-2

where

Engine Power	-	The power rating of equipment (hp)
BSFC	-	Brake Specific Fuel Consumption (BSFC) by engine power rating (lb diesel/hp-hour) based on US EPA NONROAD model documentation (US EPA 2010b, Table A4)
Diesel Density	-	Density of diesel fuel (0.85 kg/L).

F.4.1.2 On-Road Diesel Combustion Equipment

GHG emissions from on-road equipment are from on-highway haul trucks, pick up trucks, water trucks, fuel trucks, reagent trucks, welding trucks, crew change vehicles, etc. The list of on-road equipment and their operating hours for the mine preproduction and operation were provided by Q'Pit (Q'Pit 2019) whereas the list of on-road equipment/operating hours used for processing plant and tailings management facility construction were provided by Ausenco (Ausenco 2019a and Ausenco 2019b). On-road diesel exhaust GHG emissions were estimated based on the MOVES2014a model derived emission factors, road length, number of trips per day and operating hours.

Emission factors for the on-road diesel equipment were derived from the MOVES2014a model for a rural unrestricted road type, including winter and summer seasons. Since MOVES2014a was originally developed for the United States, a surrogate US county and state (Hill County, Montana) was selected to represent the Project in terms of local meteorological conditions. The model was run for a rural unrestricted road type that represents the provincial, access and haul roads, for winter and summer seasons. The emission factors derived from the MOVES2014a model are presented inTable F-2 and Equation F-3 was used to determine the emission rate.

The GHG emissions from on-road equipment are calculated using the following equation:

$$Emission\ (tonnes/year) = Road\ Length\ (km) \times Round\ Trip\ Factor(2) \times Number\ of\ Trips \left(\frac{trips}{day}\right) \times Annual\ Operating\ days \left(\frac{day}{year}\right) \times Emission\ Factor\ \left(\frac{g}{VMT}\right) \times Unit\ Conversion\ \left(0.621\frac{m}{km}\right) \times Unit\ Conversion\ \left(\frac{tonnes}{10^6 g}\right)$$

Equation F-3

where

Emission	-	Annual emission rate (tonnes/year)
Road Length	-	Road length (km)
Number of Trips	-	Number of trips per equipment per day (trips/day)
Round Trip Factor (2)	-	A factor of 2 accounting for a round trip distance
Operating days	-	Equipment operating days per year (days/year)
Emission Factor	-	Species-specific emission factor based on MOVES2014a (g/VMT)

Table F-2 On-Road Diesel Combustion GHG Emission Factors

Equipment Description	CO_2	CH_4	N_2O
	(g/VMT)		
Winter [a, b]			
Passenger Truck	590	0.0214	0.00146
School Bus	862	0.0261	0.00191

Single Unit Long-haul Truck	805	0.0393	0.00191

Table F-2 On-Road Diesel Combustion GHG Emission Factors

Equipment Description	CO_2	CH_4	N_2O
	(g/VMT)		
Combination Long-haul Truck	1743	0.0353	0.00191

NOTES:
[a] Emission factors derived from MOVES2014a (US EPA 2015)
[b] Winter is assumed 6 months: November to April
[c] Summer is assumed 6 months: May to October.

F.4.1.3 Blasting

Packaged gel emulsion products will be used for blasting during construction and the ammonium nitrate fuel oil emulsion explosives will be used during operation. During operation, all the explosives will bemanufactured at the MacLellan site. The amount of explosives consumed and the number of holes per blast during mine preproduction and operation is provided by Q'Pit (Q'Pit 2019). For processing plant construction, it was assumed that 20% of the mine preproduction blasting explosives will be used.

During operation, the Project will use an ammonium nitrate fuel oil emulsion for blasting and it was assumed that the same type of explosives will be used during construction. Blasting GHG emissions were estimated based on Mining Association of Canada (MAC) blasting emission factors (MAC, 2014), number of holes per blast, number of blasts in a year, and explosives consumption per blast. Equation F-4 was used to determine the emission rate and the emission factors from MAC are presented in Table F-3.

The GHG emissions from blasting are calculated using the following equation:

$$\begin{aligned} &Emission\ (tonnes/year) \\ &\quad = \left(Number\ of\ holes\ per\ blast \times Explosive\ Usage \left(\frac{kg\ of\ explosives}{hole}\right)\right. \\ &\quad \times Annual\ blasting\ days \left(\frac{day}{year}\right) \times Emission\ Factor \left(\frac{kg}{kg\ of\ explosives}\right)\Bigg) \\ &\quad / \left(Unit\ Conversion \left(\frac{tonnes}{1000\ kg}\right)\right) \end{aligned}$$

Equation F-4

where

Emission	-	Annual emission rate (tonnes/year)
Explosive Usage	-	Amount of explosives used per hole (kg explosives/hole)
Emission Factor	-	MAC emission factor (kg CO_2/kg of explosives)

Table F-3 Blasting GHG Emission Factor

Activity Description	CO_2	CH_4	N_2O
	kg/kg of Explosives		
Explosives Detonation	0.189	—	—

NOTES

“—"Indicates no emission factor is available.

F.4.1.4 Land Clearing

Land clearing will involve the removal of trees and other vegetation. The estimated area to be clearedof 1,049 ha was obtained from the documents provided by Ausenco of which 187 ha is associated with Gordon site and 861 ha is for MacLellan site. The cleared biomass is assumed to be open burnt with no salvage.

Land clearing and burning GHG emissions were estimated using Manitoba-specific emission factors, salvageable merchantable timber, and the vegetated area. The emission factors were derived by Natural Resources Canada (NRCan) for deforestation activities in Manitoba (NRCan 2017) as part of the 2017 National Inventory Report. Emission factors were derived for four terrestrial ecozones in Manitoba. Based on the location of the Project, the emission factor for Boreal Shield West was used for this assessment. The emission factors are based on salvage uprooting and burning activities. The emissions from land clearing activities are conservatively assumed to be non biogenic and added to the Project emissions.The GHG emission from decay of biomass are not included for this assessment as the objective would be to burn the majority of biomass material cleared leaving negligible amounts of residual material to decay.. Equation F-5 was used to determine the emission rate and the emission factors from NRCan are presented inTable F-4

GHG emissions from land clearing were divided by the two years of Project construction to estimate an annual GHG emission contribution.

The GHG emissions from land clearing are calculated using the following equation:

$$Emission\ (tonnes) = Land\ Cleared\ Area\ (ha) \times Emission\ Factor\ \left(\frac{tonnes\ of\ CO2e}{ha}\right)$$

Equation F-5

where

Emission	-	Total emission from land clearing (tonnes)
Emission Factor	-	Land Clearing emission factor (salvage uprooting and burn) for Boreal Shield West ecoregion (tonnes CO_2e/ha)

Table F-4 Land Clearing GHG Emission Factor

Activity Description	CO_2	CH_4	N_2O	CO_2e
	tonnes/ha			
Land Clearing [a]	—	—	—	85.6

NOTES
[a] NRCAN emission factors (NRCan 2017)
[a] Emission factor includes both biogenic CO_2 and non biogenic CO_2, CH_4 and N_2O
"—"Indicates no emission factor is available.

The land clearing activities such as biomass clearing and burning impacts the forest's natural carbon sinks and will lose the GHG sequestration over time. As per Manitoba Sustainable Development (MSD), the forests make up about 26.3 million hectares of land which is about 48% of the province's total land area (MSD 2019). The total land clearing area for the Project is 1,049 ha or approximately 0.004% of the Manitoba's forest. Therefore, the loss of carbon sequestration from land clearing required for the Project would be negligible in comparison to the total carbon sequestration capacity.

F.4.2 INDIRECT GHG EMISSIONS

Indirect GHG emissions (Scope 2) are emissions from the consumption of purchased electricity that are generated offsite by sources owned or controlled by another entity (WRI 2013).

F.4.2.1 Electricity Consumption

The project will purchase electricity from Manitoba Hydro for the MacLellan site. The electricity demand for the Gordon site will be supplied by the onsite diesel generator, therefore no Scope 2 emissions are associated withthe Gordon site. BBA Inc. (BBA) stated that the average electricity demand for the MacLellan site is 16,900 kWh (BBA 2019). The Scope 2 GHG estimate assumes that the MacLellan site will be operating throughout the year (24 hours a day, 7 days a week). The Manitoba Hydro electricity consumption at the MacLellan site will commence only during operation of the Project.

The indirect GHG emissions were estimated based on the ECCC NIR Manitoba specific electricity consumption emission factors (ECCC 2019a) and the Project's annual electricity consumption. Equation F-6 was used to determine the emission rate and the emission factors from NIR are presented in Table F-5.

The indirect GHG emissions from electricity consumption are calculated using the following equation:

$$Emission\ (tonnes/year) = Annual\ Consumption\left(\frac{kWh}{year}\right) \times Emission\ Factor\ \left(\frac{g\ CO2\ eq}{kWh}\right)) / (Unit\ Conversion\ \left(\frac{tonnes}{10^6\ g}\right))$$

Equation F-6

where

Emission	-	Annual emission rate (tonnes/year)
Annual Consumption	-	Annual Electricity Consumption (kWh/year)
Emission Factor	-	ECCC electricity consumption emission factor for Manitoba (g CO_2 eq/kWh)

Table F-5 Electricity Consumption GHG Emission Factor

Activity Description	CO_2	CH_4	N_2O	CO_2e
	(g/kWh)			
Electricity Consumption [a]	—	—	—	2.1

NOTES

"—"Indicates no emission factor is available.

F.5 EMISSIONS SUMMARY

The total GHG emissions calculated from the above activities during the construction and operation phases are presented in the following subsections.

F.5.1 CONSTRUCTION

The maximum annual GHG emissions during the Project construction (i.e., Q2 2021 to Q1 2022) are presented in Table F- 6. The Project construction phase emissions from off-road diesel equipment, on-road diesel equipment, explosives detonation, and land clearing activities are approximately 80,617 tonnes/year during the peak construction year. As shown in Figure F-1, the GHG emissions from Gordon and MacLellan site for the 12-month period from Q2 Year -2 to Q1 Year -1 (i.e., Q2 2021 to Q1 2022) are 19.9% and 80.1% of the total annual emissions, respectively. During the construction phase, about 55.7% of the GHG emissions are from activities associated with land clearing followed by off-road equipment (42.4%), explosives detonation (1.1%) and on-road equipment (0.7%)(see Figure F- 2).

Table F-6 Summary of Worst-Case Year Construction GHG Emissions (Gordon and MacLellan Sites)

Activity	CO_2 (tonnes/year)	CH_4 (tonnes/year)	N_2O (tonnes/year)	CO_2e (tonnes/year)

Figure F-2 Project Worst-Case Year Construction GHG Emission Breakdown by Activity

F.5.1.1 Gordon Site Construction GHG Emissions

The maximum annual GHG emissions during the Gordon site construction are presented in Table F-7. The construction emissions from off-road diesel equipment, on-road diesel equipment, explosives detonation, and land clearing activities are approximately 16,024 tonnes/year. As shown in Figure F-3, about 50.1% of the GHG emissions for the 12-month period (i.e., Q2 2021 to Q1 2022) are from activities associated with land clearing followed by off-road equipment (46.6%), explosives detonation (1.7%) and on-road equipment (1.7%).

F.5.1.2 MacLellan Site Construction GHG Emissions

The maximum annual GHG emissions during the MacLellan site construction are presented in Table F-8. The construction GHG emission from off-road diesel equipment, on-road diesel equipment, explosives detonation and land clearing activities are approximately 64,594 tonnes/year. As shown in Figure F-4, about 57.1% of the GHG emissions for the 12-month period (i.e., Q2 2021 to Q1 2022) are from activities associated with land clearing followed by off-road equipment (41.4%), explosives detonation (1.0%) and on-road equipment (0.5%).

Figure F-4 MacLellan Site Worst-Case Year Construction GHG Emission Breakdown by Activity

F.5.2 OPERATION

The maximum annual GHG emissions during Project operation are presented in Table F-9. The operation GHG emission from off-road diesel equipment, on-road diesel equipment, and explosives detonation activities are approximately 104,885 tonnes/year. This includes the indirect GHG emissions are approximately 311 tonnes/year which are from the purchase of electricity for the MacLellan Site.

As shown in Figure F-5, the GHG emissions from Gordon (Year 2) and MacLellan (Year 7) site are 34.8% and 65.2%, respectively. During operation, about 92.2% of the GHG emissions are from activities associated with off-road equipment followed by on-road equipment (5.8%), explosives detonation (1.7%) and electricity consumption (0.3%) (see Figure F-6).

Figure F-6 Project Operation GHG Emission Breakdown by Activity

F.5.2.1 Gordon Site Operation GHG Emissions

The maximum annual GHG emissions during the Gordon site operation (Year 2) are presented in Table F-10. The operation GHG emission from off-road diesel equipment, on-road diesel equipment, and explosives detonation activities are approximately 36,546 tonnes/year. As shown in Figure F-7, about 82.9% of the operation GHG emissions at Gordon site (Year 2) are from activities associated with off-road equipment followed by on-road equipment (15.1%) and explosives detonation (2.0%). The annual GHG emissons from the 300 kW diesel generator at the Gordon site (1,976 tonnes CO_2e) are included in the off-road equipment category.

Figure F-7 Gordon Site Operation Site GHG Emissions Breakdown by Activity

F.5.2.2 MacLellan Site Operation GHG Emissions

The maximum annual GHG emissions during the MacLellan site operation (Year 7) are presented in Table F-11. The operation GHG emissions from off-road diesel equipment, on-road diesel equipment and explosives detonation activities are approximately 68,339 tonnes/year. As shown in Figure F-8, about 97.2% of the operation GHG emissions at the MacLellan site (Year 7) are from activities associated with off-road equipment followed by explosives detonation (1.5%), on-road equipment (0.9%) and electricity consumption (0.5%).

Figure F-8 MacLellan Site Worst-Case Year Operation GHG Emissions Breakdown by Activity

The overall GHG emissions from the expected lifetime of the Project operation were projected using the emissions intensity calculated from the worst-case year operation for the Gordon Site (Year 2) and the MacLellan Site (Year 7). The emission intensity is calculated based on the worst-case year emissions from both Gordon and MacLellan site and their respective mined tonnes from each site. The projected GHG emissions from both Gordon and MacLellan sites are shown in Table F-12 and Figure F 9. Gordon and MacLellan sites operation emissions over the lifetime of the Project are approximately 618,944 tCO_2e and 132,713 tCO_2e, respectively. The average annual GHG emissions from Gordon and MacLellan sites are 26,543 tCO_2e and 47,611 tCO_2e over the lifetime of the each mine site.

Table F-12 Projected Operation GHG Emissions Over the Life Time of the Project

Year	Gordon Site Emissions, tCO_2e [a]	MacLellan Site Emissions, tCO_2e [b]
1	31,351	33,379
2	36,546	38,235

Figure F-9 Projected Operation GHG Emissions Over the Lifetime of the Project

F.6 COMPARISON TO NATIONAL AND PROVINCIAL GHG EMISSIONS

Table F-13 summarizes the historical GHG emissions from Manitoba and Canada. As shown in Table F-13, most recently reported 2017 total annual GHG emissions were 21,668 kt CO_2e (provincially) and 715,760 kt CO_2e (nationally). When compared to 2005 emissions, the provincial 2017 GHG emissions have increased by 7.1%, whereas the national 2017 GHG emissions have decreased by 2.0%.

The increase in provincial 2017 GHG emissions from 2005 emissions is mainly because of the increased emissions from transportation, production & consumption of halocarbons, SF_6 and NF_3 and agricultural soils categories. The decrease in national 2017 GHG emissions from 2005 emissions is mainly because of the decreased emissions from energy and industrial process and product use.

Table F-13 National and Provincial GHG Emissions Summary

Year	Canada GHG Emissions, kt CO_2e	Manitoba GHG Emissions, kt CO_2e	Manitoba's Contribution to Canada's Total, %	Canada's Emissions change from 2005, %	Manitoba Emission change from 2005
2003	741,011	20,359	2.7%	1.4%	1.2%
2004	742,980	20,638	2.8%	1.7%	2.5%

NOTE
Provincial and national GHG emission totals for the last 15 years of available data from ECCC NIR (ECCC 2019b)

F.6.1 CONSTRUCTION

The maximum annual worst-case year construction GHG emissions from both the Gordon and MacLellan sites for the 12-month period (i.e., Q2 2021 to Q1 2022) are presented in Table F-14. The construction phase GHG emissions from off-road equipment, on-road equipment, blasting and land clearing are approximately 80.6 kt CO_2e. On an annual basis, the construction phase GHG emissions from the Project contribute approximately 0.372% and 0.0113% to the provincial and national totals respectively, based on the most recently reported 2017 provincial and national GHG emissions totals (see Table F-13).

F.6.2 OPERATION

The maximum annual worst-case year operation GHG emissions from both the Gordon and MacLellan sites are presented in Table F-17. The operation GHG emissions from off-road equipment, on-road equipment, and blasting are approximately 105 kt CO_2e. On an annual basis, the operation GHG emissions from the Project contribute approximately 0.484% and 0.0147% to provincial and national totals respectively, based on the most recently reported 2017 provincial and national GHG emission totals (see Table F-13).

[c] Emissions are expressed in kilotonnes per year (kt/y)

F.6.2.1 Gordon Site Operation GHG Emissions

The maximum annual worst-case year operation GHG emissions from the Gordon site are presented in Table F-18. The Gordon site operation GHG emissions from off-road equipment, on-road equipment, and blasting are approximately 36.5 kt CO_2e. On an annual basis, the operation GHG emissions both Gordon and MacLellan site contributes approximately 0.169% and 0.00511% to the most recently reported 2017 provincial and national GHG emission totals (see Table F-13), respectively.

Table F-18 Comparison of Estimated Worst-Case Year Operation Emissions from the Gordon Site to Provincial and National 2017 Emissions

Parameter	Units	CO_2	CH_4	N_2O	CO_2e
Operation GHG Emissions	kt/y [c]	35.8	0.000920	0.00251	**36.5**
Manitoba GHG Emissions [a]	kt/y [c]	13,328	3,933	3,910	**21,668 [b]**
National GHG Emissions [a]	kt/y [c]	571,137	92,862	38,037	**715,760 [b]**
Project operation contribution to Manitoba GHG Emissions	%	0.268%	0.0000234%	0.0000641%	**0.169%**
Project operation contribution to national GHG Emissions	%	0.00626%	0.000000991%	0.00000659%	**0.00511%**

NOTE:
[a] Provincial and national GHG emission totals from ECCC NIR (ECCC 2019b)
[b] Provincial and national GHG emission totals include other fluorinated GHGs
[c] Emissions are expressed in kilotonnes per year (kt/y)

F.6.2.2 MacLellan Site Operation GHG Emissions

The maximum annual worst-case year operation GHG emissions from the Maclellan site are presented in Table F-19. The Maclellan site operation GHG emissions from off-road equipment, on-road equipment, and blasting are approximately 68.3 kt CO_2e. On an annual basis, the operation GHG emissions both Gordon and MacLellan site contributes approximately 0.315% and 0.00955% to the most recently reported 2017 provincial and national GHG emission totals (see Table F-13), respectively.

Table F-19 Comparison of Estimated Worst-Case Year Operation Emissions from the MacLellan Site to Provincial and National 2017 Emissions

Parameter	Units	CO_2	CH_4	N_2O	CO_2e
Operation GHG Emissions	kt/y [c]	66.7	0.00178	0.00548	**68.3**
Manitoba GHG Emissions [a]	kt/y [c]	13,328	3,933	3,910	**21,668 [b]**
National GHG Emissions [a]	kt/y [c]	571,137	92,862	38,037	**715,760 [b]**
Project operation contribution to Manitoba GHG Emissions	%	0.498%	0.0000452%	0.000140%	**0.315%**
Project operation contribution to National GHG Emissions	%	0.0116%	0.00000191%	0.0000144%	**0.00955%**

NOTES:
[a] Provincial and national GHG emission totals from ECCC NIR (ECCC 2019b)
[b] Provincial and national GHG emission totals include other fluorinated GHGs
[c] Emissions are expressed in kilotonnes per year (kt/y)

1.0 INTRODUCTION

The Lynn Lake Gold Project (LLGP; or "the Project") consists of two primary deposit sites, which are both located near Lynn Lake, Manitoba: The 'Gordon' site and the 'MacLellan' site. Alamos Gold Inc. (Alamos) intends to construct (redevelop), operate and eventually close/reclaim open-pit gold mines at both of these historical mine sites. The Gordon site is located approximately 55 kilometres (km) east of Lynn Lake, Manitoba (by vehicle), and the MacLellan site is located approximately 8 km northeast of Lynn Lake (by vehicle). Lynn Lake is located approximately 820 km northwest of Winnipeg.

This Light Emission Impact Assessment (LEIA) has been completed to fulfill a requirement of the "Guidelines for the Preparation of an Environmental Impact Statement" (2017) pursuant to the *Canada Environmental Assessment Act* (2012) for the LLGP. The LEIA provides an overview of the existing conditions in the Project area and predicts the effects of proposed Project lighting on nearby receptors.

This report is presented in 10 sections. The purpose of the Light Emission Impact Assessment is provided in Section 1 and a description of the types of obtrusive light is provided in Section 2. The regulatory criteria used in the assessment is discussed in Section 3 and an overview of the existing ambient light environment in the Project area is provided in Section 4. Section 5 contains the results of a viewshed analysis and Section 6 describes the methodology, results and provides a discussion of the LEIA. Concluding remarks are provided in Section 7 with references cited listed in Section 8. Section 9 presents Stantec's Quality Management section and Section 10 provides the report limitations.

2.0 TYPES OF OBTRUSIVE LIGHT

Light associated with an industrial development is critical to the safe and efficient operation of the enterprise. Excessive or poorly designed lighting can have detrimental effects on the environment whereas careful and progressive design can achieve the operational requirements while reducing the residual impact to the environment. Good lighting meets the required levels on the designated property with low capital, maintenance and energy costs. Badly designed lighting or excessive lighting can result in three types of obtrusive lighting, generally referred to as light trespass, glare and sky glow, and are described below.

Light Trespass: The transmission of light from fixtures within a facility to the environment and sensitive receptors outside the facility. The unit of measure for light incidence, within or outside a facility, is a lux. A lux is equal to 1 lumen per square metre (lumen/m^2). Incident light mainly becomes problematic when lights located on the outside of a facility shine in through the windows of nearby residential homes at levels that can potentially disrupt sleep or distract from normal levels.

Glare: Potential environment effect in which intense, harsh, or contrasting lighting conditions can reduce the ability to see . A common example of glare is the oncoming high-beam headlights that provide ample light but result in poor visibility. The units of measure for brightness is luminous intensity, measured in candela (cd).

Sky Glow: Illumination of the sky or clouds by light sources on the surface of the earth such as street lighting, and haze in the atmosphere that replaces the natural nighttime sky with a translucent to opaque lighting dome. Sky glow is the cumulative effect of lights either emitting upward or being reflected upward by the surface plus the emission from photochemical activity in the atmosphere . The unit of measure for the brightness of the sky, including sky glow, is magnitudes per square arcsecond (mag/arcsec^2). Sky glow values range from approximately 22 mag/arcsec^2 in a rural environment where stars are abundant to approximately 17 mag/arcsec^2 in an urban environment where stars are minimally visible (CIE 2003). Due to the astronomy roots of the measure, it is inverse; that is, higher numbers are darker, and lower numbers are brighter.

In addition to the three main categories of obtrusive lighting described above, light flicker and light presence can also result in disruptive environmental effects. Light flicker refers to the periodic flickering of light sources (Scottish Executive 2007). The rate of flicker and the duration of exposure can cause over-stimulation of electrical activity to the human brain (Scottish Executive 2007). Light presence refers to where light emitted from a light source can be viewed from outside the area it was provided for (Scottish Executive 2007). In general, light presence causes minimal visual discomfort.

3.0 REGULATORY BACKGROUND AND ASSESSMENT CRITERIA

Most lighting guidelines and regulations have been directed toward the provision of suitable lighting for the safe and efficient activities of humans. For example, street lighting, indoor lighting and lighting around industrial plants are subjects of various guidelines to facilitate a safe work environment. Currently there are no legally binding requirements (e.g., regulations) in Manitoba to regulate obtrusive light being emitted from facilities.

Various international organizations, including the International Dark Sky Association (IDA) and the *Commission Internationale de L'Éclairage* (CIE), also known as the International Commission on Illumination, have developed guidelines and recommendations to limit light pollution and associated impacts to humans and wildlife. The Illuminating Engineering Society of North America (IESNA) have adopted such guidelines and recommendations for use in developing new outdoor lighting. Each of these organizations and their guidelines are further described in Sections 3.1 and 3.2.

3.1 THE COMMISSION INTERNATIONAL DE L'ECLAIRAGE (CIE)

The Commission International de L'Eclairage (CIE), also known as the International Commission on Illumination, is an independent non-profit organization serving member countries on a voluntary basis. Since its inception in 1913, CIE has become a professional organization and is currently recognized by the International Organization for Standardization (ISO) as an international standardization body relating to matters on light and lighting, color and vision, photobiology and image technology (CIE 2017).

CIE has established guidelines for light trespass and glare for various levels of urbanization. These guidelines have been adopted in Great Britain, in particular by the Scottish Executive in their guidance document “Controlling Light Pollution and Reducing Lighting Energy Consumption” (Scottish Executive 2007).

The values represented in the guidelines are based on environmental zones and time of day. Five environmental zones have been established by the CIE (CIE 2017) as a basis for outdoor lighting. The five zones are listed in Table 3-1.

Table 3-1 Environmental Lighting Zones

Zone	Lighting Environment	Examples
E0	Intrinsically Dark	IDA Dark Sky Parks
E1	Dark	Relatively uninhabited rural areas
E2	Low district brightness	Sparsely inhabited rural areas
E3	Medium district brightness	Well inhabited rural and urban settlements
E4	High district brightness	Town and city centres and other commercial areas
Source: CIE 2017		

The maximum values recommended by CIE for light trespass (vertical illuminance) on properties by environmental lighting zone and time of day are presented in Table 3-2.

Table 3-2 Recommended Maximum Values of Light Trespass (Vertical Illumination) on Properties per Environmental Zones

Application Conditions	Environmental Lighting Zones				
	E0	**E1**	**E2**	**E3**	**E4**
Pre-curfew (19:00 – 23:00)	NA	2 lux	5 lux	10 lux	25 lux
Post-curfew (23:00 – 6:00)	NA	0.1* lux	1 lux	2 lux	5 lux
NA – Not Applicable *if the installation is for public (i.e. road) lighting then this value may be up to 1 lux. Source: CIE 2017					

The maximum values recommended by CIE for glare (intensity of luminaires) in designated directions by environmental lighting zone and time of day are presented in Table 3-3. The limits are dependent on the distance (d) between the observer and the luminaire and the projected area (A_p) of the bright part of the luminaire in the direction of the observer.

Table 3-3 Recommended Maximum Values for Glare (Intensity of Luminaires) in Designated Directions

Light Parameter	Application Conditions	Luminaire Group (projected area A_p in m^2)				
		$0 < A_p \leq 0.002$	$0.002 < A_p \leq 0.01$	$0.01 < A_p \leq 0.03$	$0.03 < A_p \leq 0.13$	$0.13 < A_p \leq 0.50$
Maximum Luminous Intensity Emitted by Luminaire (cd)	E0					
	Pre-curfew	0	0	0	0	0
	Post-curfew	0	0	0	0	0
	E1

	Pre-curfew	0.86 * *d*	1.9 * *d*	3.8 * *d*	7.5 * *d*	15 * *d*
	Post-curfew	0.29 * *d*	0.63 * *d*	1.3 * *d*	2.5 * *d*	5.1 * *d*
	E4					
	Pre-curfew	1.4 * *d*	3.1 * *d*	6.3 * *d*	13 * *d*	26 * *d*
	Post-curfew	0.29 * *d*	0.63 * *d*	1.3 * *d*	2.5 * *d*	5.1 * *d*

d is the distance between the observer and the glare source in meters
Source: CIE 2017

To limit the potential for sky glow CIE recommends maximum values for the upward light ratio (ULR) of luminaires and for the upward flux ratio (UFR) of installations (four or more luminaries). The UFR takes into account the light that is reflected upwards based on the reflecting surface as well as from the luminaire, whereas the ULR only considers the light directed upwards from the luminaire itself. For this purpose of this assessment the ULR is considered, as the Project will contain multiple luminaries with the potential to contribute to sky glow.

The CIE maximum values of UFR are presented in Table 3-4.

Table 3-4 Maximum Values of Upward Flux Ratio of Installation

Light Parameter	Type of Installation	Environmental Lighting Zones				
		E0	E1	E2	E3	E4
Upward Flux Ratio (%)	Road	NA	2	5	8	12
	Amenity	NA	NA	6	12	35
	Sports	NA	NA	2	6	15

NA – Not applicable
Source: CIE 2017

Reference levels for sky glow are shown in Table 3-5 (Berry 1976). The higher the number, the more the sky is dominated by the natural background, and the lower the number, the greater the degree of sky glow caused by the reflection of lighting from the atmosphere.

Table 3-5 Reference Levels of Sky Glow

Sky Glow (mag/arcsec^2)	Corresponding Appearance of the Sky
21.7 (Rural)	The sky is covered with stars that appear large and close. In the absence of haze, the Milky Way can be seen to the horizon. The clouds appear as black silhouettes against the sky.
21.6	The above with a glow in the direction of one or more cities is seen on the horizon. Clouds are bright near the city glow.
21.1	The Milky Way is brilliant overhead but cannot be seen near the horizon. Clouds have a greyish glow at the zenith and appear bright in the direction of one or more prominent city glows.
20.4	The contrast to the Milky Way is reduced and detail is lost. Clouds are bright against the zenith sky. Stars no longer appear large and near.
19.5	Milky Way is marginally visible, only near the zenith. Sky is bright and discoloured near the horizon in the direction of cities. The sky looks dull grey.
(18.5 Urban)	Stars are weak and washed out and reduced to a few hundred. The sky is bright and discoloured everywhere.
Source: Berry 1976	

The CIE maximum values for light trespass and glare have been used in this assessment to identify potential effects on nearly receptors (refer to Section 6.3).

3.2 OTHER RELEVANT STANDARDS AND GUIDELINES

There are a number of other organizations whose mandate is aimed at providing awareness of the potential effects from light pollution and providing means to reduce light pollution including. These organizations include, but are not limited to:

- Illuminating Engineering Society (IES)
- International Dark Sky Association (IDA)

The Illuminating Engineering Society (IES) was founded in 1906 and is composed of members with an interest in good lighting, lighting designers and architects, consultants, distributors and wholesalers working in affiliated lighting fields, utilities and energy services, and people in government and education. The IES "seeks to improve the lighted environment by bringing together those with lighting knowledge and by translating that knowledge into actions that benefit the public" (IES 2017). The IES – North America chapter, has adopted the use of the environmental zones originally proposed by the CIE, and recommends their implementation in designing new outdoor lighting.

The IES produced "The Lighting Handbook" to guide and give recommendations for designing, installing, and maintain lighting systems. The handbook presents recommended guidelines only, as the IES is not an authoritative entity. The tenth edition (2011) of the handbook provides information and recommendations for guiding designers and users of light systems with a focus on both reducing lighting energy expectations and the need for effective luminous environments. This handbook is recognized internationally as a best practices resource.

The International Dark Sky Association (IDA) is closely associated with astronomical interests, and publishes a number of model municipal guidelines, fact sheets, and other material for public education on the benefits of reducing light pollution.

4.0 EXISTING CONDITIONS

4.1 BASELINE MONITORING APPROACH

In October 2015 baseline light monitoring was completed at five locations surrounding the Gordon and MacLellan sites to quantify the existing ambient light surrounding the Project. Baseline light monitoring at each site included measurements of illuminance (lux) and sky glow. Illuminance was measured using a conventional, integrating hemispherical light meter (Extech EA33) with a resolution of 0.01 lux. Sky glow was measured using a Unihedron Sky Quality Meter with lens (SQM-L). This meter was developed for astronomical applications to document the level of sky brightness, with the measurement consisting of light within an approximate 60-degree solid angle of sky. This instrument measures in magnitudes/square arc-second (mag/arcsec^2). In addition to the light measurements, photographs were made at all but one monitoring location (VP3) to document the view during the day and during the night using a high quality (Canon 60D) digital camera. At VP3, the site was dark to the point that landscape features were not properly resolving in the photography.

The locations designated for the baseline light survey and the rationale for their selection are presented in Table 4-1.

Table 4-1 Baseline Ambient Light Measurement Locations

Location No.	Site Location (UTM Zone 10U)		Selection Rationale
	Easting (m)	Northing (m)	
VP1 – Burge Lake	375529	6308046	Important recreation area about 4 km west of MacLellan Site
VP2 – Lynn Lake Project end (north)	375605	6303376	At north edge of town, about 5 km SSW of MacLellan Site
VP3 – Along Highway	381280	6304656	Closest point along Highway to MacLellan Site (~2 km), representing total dark site.
VP4 – Black Sturgeon Reserve Road	405612	6297833	Marcel Colomb First Nation Monitoring Site
VP5 – Lynn Lake, Main Street	375236	6302819	Representative of urban centre, Lynn Lake

4.2 BASELINE MONITORING RESULTS

Results of sky glow measurements for each baseline light monitoring location are shown in Table 5.2. Measurements of incident light were below the meter's detection level of 0.1 lux at each monitoring location, and therefore not presented in Table 4-2.

The photographs collected during the baseline ambient light monitoring survey were provided in the "Lynn Lake Gold Project (LLGP): Ambient Lighting Baseline Technical Data Report" (Stantec Consulting ltd. 2017).

Table 4-2 Average Sky Glow Readings

Site	Sky Brightness (mag/arcsec^2)	Date
VP1 – Burge Lake	19.67 19.60 19.61 19.86 19.61 19.78	2015-10-14 and 2015-10-15
VP2- Lynn Lake, Project end (north)	12.98 14.07 17.69 18.86	2015-10-14
VP3 – Along Highway	19,27 19.30 19.28	2015-10-14
VP4 – Black Sturgeon Reserve Road	20.27 18.62 18.17 19.02	2015-10-14
VP5 – Lynn Lake, Main Street	15.38 14.38 12.77	2015-10-14

The current light environment surrounding the Project is typical of light levels in remote towns and villages. Sky glow measurements were more comparable to urban or suburban environments, as classified in Table 4-2, due to the presence of Aurora Borealis both nights measurements were taken. Measurements were consistent with other small towns and villages where light pollution is typically not a priority for control. Streetlights, for example, are not necessarily selected and located with control in mind; older "cobra" style luminaires that emit a substantial fraction of light above the horizontal are used, rather than modern "horizontal cut-off" luminaires.

The baseline survey determined that the light impacting the community of Lynn Lake and the Black Sturgeon Reserve is the light that is generated within the community and reserve, not from other sources, such as industry, outside of these areas, and that the dark sky is visible within a few kilometres.

5.0 VIEWSHED ANALYSIS

A viewshed analysis was conducted to illustrate whether Project components would be visible from each of the five viewpoints considered during the baseline light monitoring as well as three additional viewpoints of interest from a recreational activity perspective. The three additional viewpoints included the Keewatin River west of the MacLellan site, an elevated location along PR 391 in between the Gordon and MacLellan sites, and the Hughes River. The locations of each of the additional viewpoints are presented in Maps A-6 to A-8 in Appendix A.

The viewshed analysis was conducted using the Viewshed Analysis tool in ArcMap. The viewshed analysis estimates the change in elevation from each viewpoint location to the Gordon and MacLellan sites. To evaluate if the Gordon or MacLellan sites and Project components would be visible from each viewpoint, the software estimates the change in elevation at a number of locations between the viewpoint location and the Project location to determine if there is a line of sight. If there are locations in-between with higher elevation, the line of sight to the Project is considered blocked, and therefore the Project components would not be visible from that location.

The viewshed analysis performed for each viewpoint are graphically presented in Maps A-1 to A-8 in Appendix A.

The results of the viewshed analysis show that the Project components located at the Gordon and MacLellan sites would not be visible at any of the five viewpoint locations considered during the baseline light monitoring. Of the viewpoints considered with respect to recreational activities, it was determined that portions of the Project Development Area for the MacLellan site could be visible from the Keewatin River and along PR 391, in between the Gordon and MacLellan sites.

6.0 LIGHT IMPACT ASSESSMENT

6.1 OVERVIEW OF LIGHTING DESIGN

Stantec developed a preliminary Light Plan to incorporate into the light modelling. The preliminary Light Plan was developed using recommended minimum lighting levels provided by the Illuminating Engineering Society (IES) of North America's IES Lighting Handbook for outdoor worksite lighting.

The AGi32 software package by Lighting Analysts was used in the development of the Project's Light Plan. Features of AGi32 include:

- Creating 3D models of Project site layouts to scale that incorporate distribution optics, mounting height, tilt, rotation, and electrical power.
- Using international standard photometry data for luminaires.
- Providing realistic textures and colours for objects and buildings created in the 3D model.
- Inserting calculation areas and points, via 3D objects, into the model to represent receptor locations.

To initiate the process, Stantec imported Project CAD files, indicating the location of the Project infrastructure and equipment, as well as site and regional elevation data. The design documents and additional Project mapping files were then used to create 3-dimensional buildings and infrastructure for each site. The amount of light required at each site, known as illuminance targets, was then acquired from IES recommended practices based on the different work areas, by assigning each area a classification, and assuming that the Project Area would fall in the Low Ambient Lighting (LZ1) zone. The LZ1 zone classification considers that the vision of existing human residents and users is adapted to low light levels.

Once the project components were incorporated into the AGi32 model software, and the work classifications were set, the type of light fixtures required to meet the minimum recommended lighting level for each classified work area were identified in consideration of the IES criteria and preliminary engineering details from Alamos. The appropriate number and locations of the fixtures were also determined.

The preliminary Light Plan for the Gordon and MacLellan sites is presented in Maps 6-1 and 6-2, respectively. The characteristics of the light fixtures are provided in Tables B-1 and B-2 in Appendix B. Cut sheets for the luminaires are also included in Appendix B.

6.2 PREDICTIVE MODELLING APPROACH

The AGi32 model used to develop the Light Plan for the Project was subsequently used to predict levels of light trespass (i.e. luminance) and glare (i.e. intensity) at off-site receptor locations.

Residences located nearest the Project Development Areas were considered as receptor locations for the predictive modelling. Receptors that were located in close proximity to one another were grouped together to form a receptor “cluster”. Other areas that were identified as Indigenous fishing camps and trapping areas were also considered in the assessment, as individual receptors. The locations of each individual receptor and the receptor clusters considered in the modelling are presented on Map 6-3.

Within the model, receptor locations were created from a standard sized building object and placed with the broad side of the building exposed to the highest concentration of lighting from the mine sites. As the local terrain is heavily forested, trees were incorporated into the model so that the final predictions are realistic of coverage consistent with typical coniferous forested areas.

The results of the light modelling for light trespass and glare were compared against the baseline measurements (refer to Section 4) and analyzed to determine compliance against the CIE guidelines for luminance and luminaire intensity (refer to Section 3.2).

As determined through the viewshed analysis there is no direct line of sight between each viewpoint location considered in the baseline light monitoring study (VP1 – 5) and the highest Project component/ infrastructure. According to the CIE, illuminance (i.e. light trespass) and luminous intensities (i.e., glare) calculations are not required for receptors were a direct line of sight between the source of the light and the receptor is not possible due to the presence of foliage, buildings fences, etc. As noted above, based on the current Light Plan the luminaries proposed for the Project are not visible at each of the five viewshed points (VP1 – 5) considered during the baseline light monitoring. The modelling considered additional receptor locations (i.e. not just the five viewshed locations considered for the baseline light monitoring study); and the predicted levels of light trespass (i.e. illuminance) and glare (i.e. luminous intensities) were calculated and presented in Section 6.3.

6.3 PREDICTIVE MODELLING RESULTS

The predicted levels of light trespass and glare resulting from the operation of the Project for the residential receptor clusters are presented in Table 6-1. The predicted levels of light trespass and glare from the operation of the Project at the individual receptor locations (including sparsely located residential areas, fishing camps and trapping areas) are provided in Table C-1 in Appendix C. The values presented in Tables 6-1 and C-1 represent the overall maximum predicted value and not an average.

Table 6-1 Predicted Levels of Light Trespass and Glare – Receptor Clusters

Receptor Cluster ID	Light Trespass (lux)	Glare (cd)
Cluster 1	<0.001	<0.001
Cluster 2	0.0002	<0.001
Cluster 3	<0.001	<0.001
Cluster 4	0.0001	<0.001
Cluster 5	0.0001	<0.001
Lynn Lake Cluster North	<0.001	<0.001
Lynn Lake Cluster Central	<0.001	<0.001
Lynn Lake Cluster South	<0.001	<0.001

Based on the CIE environmental lighting zones (refer to Table 3-1), the area surrounding the Project could be considered as an E2 environmental lighting zone; a sparsely inhabited rural area with low district brightness. Considering the results presented in Table 6-1 and C-1 in Appendix C, the predicted levels of light trespass (i.e. illuminance) and glare (i.e. luminous intensity) are below CIE criteria for an E2 environmental lighting zone. The light design for the Project explicitly incorporated CIE criteria to limit illuminance off-site and reduce incidence of light trespass.

The Project's light design incorporates the use of full cut-off LED luminaires and was developed in accordance with the guidelines and recommendations of the IDA and CIE. Therefore, the Project is expected to have a small contribution to the existing sky glow.

7.0 CONCLUSIONS

Light associated with an industrial development is critical to the safe and efficient operation of the enterprise. Excessive or poorly designed lighting can have detrimental effects on the environment whereas careful and progressive design can achieve the operational requirements while reducing the residual impact to the environment.

The current light environment surrounding the Project is typical of light levels in remote towns and villages. The light that does affect the nearest communities is the light that is generated within the community, not from other sources, such as industry.

This Light Emission Impact Assessment shows that the light emissions from the operation of the Project can be designed to be within CIE guidelines at the nearest receptor locations and communities.

10.0 LIMITATIONS

This Technical Modelling Report entitled Lynn Lake Gold Project, Light Emissions Impact Assessment was prepared by Stantec Consulting Ltd. ("Stantec") for the account of Alamos Gold Inc. (the "Client") to support the approvals and permitting process for the Lynn Lake Gold Project in Lynn Lake, Manitoba. In connection thereto, this document may be reviewed and used by the federal and provincial government agencies participating in the approvals and permitting process in the normal course of their duties; and stakeholders may provide comment as part of the regulatory approvals process. Except as set forth in the previous sentence, any reliance on this document by any third party for any other purpose is strictly prohibited. The material in it reflects Stantec's professional judgment in light of the scope, schedule and other limitations stated in the document and in the contract between Stantec and the Client. The opinions in contents of the document are based on conditions and information existing at the time the document was published and do not take into account any subsequent changes. In preparing the document, Stantec did not verify information supplied to it by others. Any unauthorized use that a third party makes of this document is the responsibility of such third party. Such third party agrees that Stantec shall not be responsible for costs or damages of any kind, if any, suffered by it or any other third party as a result of decisions made or actions taken based on unauthorized use of this document.

Appendix B LIGHT PLAN DETAILS

Lumark

DESCRIPTION

The patented Lumark Crosstour™ MAXX LED wall pack series of luminaries provides low-profile architectural style with super bright, energy-efficient LEDs. The rugged die-cast aluminum construction, back box with secure lock hinges, stainless steel hardware along with a sealed and gasketed optical compartment make Crosstour impervious to contaminants. The Crosstour MAXX wall luminaire is ideal for wall/surface, inverted mount for facade/canopy illumination, perimeter and site lighting. Typical applications include pedestrian walkways, building entrances, multi-use facilities, industrial facilities, perimeter parking areas, storage facilities, institutions, schools and loading docks.

Catalog #		Type
Project

SPECIFICATION FEATURES

Construction
Low-profile LED design with rugged one-piece, die-cast aluminum back box and hinged removable door. Matching housing styles incorporate both a full cutoff and refractive lens design. Full cutoff and refractive lens models are available in 58W, 81W and 102W. Patent pending secure lock hinge feature allows for safe and easy tool-less electrical connections with the supplied push-in connectors. Back box includes four 1/2" NPT threaded conduit entry points. The back box is secured by four lag bolts (supplied by others). External fin design extracts heat from the fixture surface. One-piece silicone gasket seals door and back box. Not recommended for car wash applications.

Optical
Silicone sealed optical LED chamber incorporates a custom engineered reflector providing high-efficiency illumination. Full cutoff models integrate an impact-resistant molded refractive prism optical lens assembly meeting requirements for Dark Sky compliance. Refractive lens models incorporate a molded lens assembly designed for maximum forward throw. Solid state LED Crosstour MAXX luminaries are thermally optimized with eight lumen packages in cool 5000K, neutral 4000K, or warm 3000K LED color temperature (CCT).

Electrical
LED driver is mounted to the die-cast aluminum housing for optimal heat sinking. LED thermal management system incorporates both conduction and natural convection to transfer heat rapidly away from the LED source. 58W, 81W and 102W models operate in -40°C to 40°C [-40°F to 104°F]. High ambient 50°C [122°F] models available in 58W and 81W models only. Crosstour MAXX luminaires maintain greater than 89% of initial light output after 72,000 hours of operation. Four half-inch NPT threaded conduit entry points allow for thru-branch wiring. Back box is an authorized electrical wiring compartment. Integral LED electronic driver incorporates surge protection. 120-277V 50/60Hz, 480V 60Hz, or 347V 60Hz electrical operation. 480V is compatible for use with 480V Wye systems only.

Emergency Egress
Optional integral cold weather battery emergency egress includes emergency operation test switch (available in 58W and 81W models only), an AC-ON indicator light and a premium extended rated sealed maintenance-free nickel-metal hydride battery pack. The separate emergency lighting LEDs are wired to provide redundant emergency lighting. Listed to UL Standard 924, Emergency Lighting.

Area and Site Pole Mounting
Optional extruded aluminum 6-1/2" arm features internal bolt guides for supplied twin support rods, allowing for easy positioning of the fixture during installation to pole. Supplied with round plate adapter plate. Optional tenon adapter fits 2-3/8" or 3-1/2" O.D. Tenon.

Finish
Crosstour MAXX is protected with a super TGIC carbon bronze or summit white polyester powder coat paint. Super TGIC powder coat paint finishes withstand extreme climate conditions while providing optimal color and gloss retention of the installed life.

Warranty
Five-year warranty.

NOTES:
1. DesignLights Consortium® Qualified and classified for both DLC Standard and DLC Premium, refer to www.designlights.org for details.
2. Not available with HA option.
3. Deep back box is standard for 347V, 480V, CBP, PMA, MS-L20 and MS/DIM-L20.
4. Not available with CBP option.
5. Thru-branch wiring not available with HA option or with 347V.
6. Only for use with 480V Wye systems. Per NEC, not for use with ungrounded systems, impedance grounded systems or corner grounded systems (commonly known as Three Phase Three Wire Delta, Three Phase High Leg Delta and Three Phase Corner Grounded Delta systems).
7. Not available with MS-L20 and MS/DIM-L20 options.
8. Use PC2 with 347V or 480V option for photocontrol. Factory wired to 208-277V lead.
9. Customer is responsible for engineering analysis to confirm pole and fixture compatibility for all applications. Refer to our white paper WP513001EN for additional support information.
10. For use in downlight orientation only. Optimal coverage at mounting heights of 9'-20'.
11. 120V thru 277V only.
12. Factory set to 50% power reduction after 15-minutes of inactivity. Dimming driver included.
13. Includes integral photo sensor.
14. The FSIR-100 configuration tool is required to adjust parameters including high and low modes, sensitivity, time delay, cutoff, and more. Consult your lighting representative at Eaton for more information.
15. 120V or 277V operation only.
16. Operating temperatures -20°C to 25°C.
17. Not available in XTOR12B or XTOR12BRL models.
18. Replace XX with housing color.

Key features & benefits

Features
- Energy efficient alternative to hazardous location Metal Halide and High Pressure Sodium
- Designed for outdoor, hazardous, Marine, low-bay and flood
  applications
- Gray powder coat finish
- Multiple distribution patterns, Type V
- Selection of Frosted film, 16°, 70° or 120° Lens
- CCT of 5000K
- Selection of mounting style
- Tamper-proof screws
- > 120,000 hours Rated Lifetime Projection (L70)

Construction
- Cooper-free cast aluminum housing
- Captive stainless steel fasteners and insert
- 24 high-power LED's

Electrical
- 50W (6400 Lumens), 80W (9000 Lumens), 105W (11000 Lumens)
- 120-277V
- 277-480V (6400 Lumens only)

Options
- Mounting: Ceiling, Pendant, Yoke, Wall, Straight or Angled Stanchion
- Cord with Blunt End
- Lens Guard
- Black or White finish

DESCRIPTION

The Ventus™ LED area luminaire provides uncompromising optical performance and outstanding versatility for a wide variety of area and roadway applications. Patented modular LightBAR™ technology delivers uniform and energy conscious illumination to walkways, parking lots, roadways, building areas and any security lighting application. UL/cUL Listed for wet locations.

Catalog #		**Type**

SPECIFICATION FEATURES

Construction
Die-cast aluminum frame secures thermally conductive, extruded aluminum heat sink to independent electrical chamber. Heavy-wall, die-cast aluminum housing and door isolates driver components for cooler operation. The unique construction allows for passive cooling and natural cleaning of the extruded heat sink ensuring reliable operation at 40°C high ambient conditions. Stainless steel fasteners and hinging allow access to electrical components for installation and maintenance. Optional tool-less hardware available for ease of entry into electrical chamber.

Optics
Choice of twelve patented, high-efficiency AccuLED Optics™ distributions. Optics are precisely designed to shape the light output, maximizing efficiency and application spacing. AccuLED Optics technology creates consistent distributions with the scalability to meet customized application requirements. Offered Standard in 4000K (+/- 275K) CCT and minimum 70 CRI. Optional 3000K CCT, 5000K CCT and 5700K CCT. For the ultimate level of spill light control, an optional house-side shield accessory can be field or factory installed. The house-side shield is designed to seamlessly integrate with the SL2, SL3 or SL4 optics.

Electrical
LED drivers mount to die-cast aluminum back housing for optimal heat sinking, operation efficacy, and prolonged life. Standard drivers feature electronic universal voltage (120-277V 50/60Hz), 347V 60Hz or 480V 60Hz operation. 480V is compatible for use with 480V Wye systems only. Greater than 0.9 power factor, less than 20% harmonic distortion, and is suitable for operation in -40°C to 40°C ambient environments. All fixtures are shipped standard with 10kV/10kA common – and differential – mode surge protection. LightBARs feature an IP66 enclosure rating and maintain greater than 95% lumen maintenance at 60,000 hours per IESNA TM-21. Occupancy sensor and dimming options available.

Mounting
Internal mast arm mount accepts a 1-1/4” to 2” (1-5/8” to 2-3/8” O.D.) horizontal tenon, while a two-bolt clamping mechanism secures fixture. Cast-in leveling guides provide +/-5° vertical leveling adjustment. Optional cast aluminum 6” arm includes bolt guides allowing for easy positioning of fixture during installation to pole or wall surface.

Finish
Cast components and arm finished in a five-stage super TGIC polyester powder coat paint, 2.5 mil nominal thickness for superior protection against fade and wear. Standard colors include black, bronze, grey, white, dark platinum and graphite metallic. RAL and custom color matches available. Consult the McGraw-Edison Architectural Colors brochure for the complete selection.

Warranty
Five-year warranty.

NOTES:
1. Customer is responsible for engineering analysis to confirm pole and fixture compatibility for all applications. Refer to our white paper WP513001EN for additional support information.
2. Standard 4000K CCT and nominal 70CRI.
3. 21 LED LightBAR powered at 350mA, 7 LED LightBAR powered at 1A.
4. Not available with HA option.
5. Only for use with 480V Wye systems. Per NEC, not for use with ungrounded systems, impedance grounded systems or corner grounded systems (commonly known as Three Phase Three Wire Delta, Three Phase High Leg Delta and Three Phase Corner Grounded Delta systems).
6. Must specify DIM option to add dimming driver(s). Only available in E02-E06 and F02-F06.
7. Not available with DIM option or MS/DIM-LXX.
8. Not available with motion sensor. 120 - 277V only.
9. Requires two electrical circuits to luminaire. See LightBAR operation table for additional information.
10. Consult factory before ordering in combination with MS-LXX or MS/X-LXX options.
11. Not available in 347V or 480V.
12. Not available with 5MQ, 5WQ or 5XQ distributions. Not available with HSS option.
13. Extended lead times apply.
14. Sensor housed in external box mounted to the luminaire. Available in E02-E12 and F02-F12 configurations. Replace XX with mounting height in feet for proper lens selection, (e.g., MS-L25). Consult factory for additional information.
15. Sensor housed in external box mounted to the luminaire. Available in E02-E12 and F02-F12 configurations. Replace X with number of bars operating in low output mode and replace XX with mounting height for proper lens selection, (e.g., MS/3-L25). Maximum 4 bars in low output mode. Consult factory for additional information.
16. Not available with HA option. Only available in E02-E06 and F02-F06. Includes Dimming Drivers. Not available in 347V or 480V.
17. Replace XX with mounting height in feet for proper lens selection, (e.g., MS/DIM-L25).
18. Available in E02-E06 and F02-F06 only.
19. Only for use with SL2, SL3 and SL4 distributions. Not available with L90 or R90 options.
20. Replace XX with color suffix.
21. One required for each LightBAR. Not available with L90 or R90 options.

Lynn Lake Gold Project, Noise and Vibration Impact Assessment

Technical Modelling Report

April 7, 2020

Prepared for:

Alamos Gold Inc.
Brookfield Place, 181 Bay Street
Suite 3910
Toronto, ON M5J 2T3

Prepared by:

Stantec Consulting Ltd.
500-311 Portage Avenue
Winnipeg, MB R3B 2B9

111473008

Table of Contents

LIST OF TABLES

LIST OF MAPS (AT END OF REPORT)

LIST OF APPENDICES

Abbreviations

%HA	percent highly annoyed
Alamos	Alamos Gold Inc.
C	confinement constant
D	distance from equipment to receptor
dB or dBL or dBZ	linear (unweighted) decibel sound level
dBA	a-weighted decibel sound level
dBC	c-weighted decibel sound level
EA	Environmental Assessment
EIS	Environmental Impact Statement
FTA	Federal Transit Administration
ID	identification
km	kilometres
L	Litre
LAA	Local Assessment Area
L_d	daytime equivalent sound level
L_{dn}	day-night average sound level
$L_{dn, adjusted}$	day-night average sound level with adjustments made for certain characteristics of sound such as expectation of “peace and quiet”, tonality, or impulsiveness
L_{eq}	equivalent sound level
$L_{eq, 1hr}$	one-hour equivalent sound level
LFN	low frequency noise
LLGP	Lynn Lake Gold Project

L_n	nighttime equivalent sound level
$L_{v\ distance}$	root mean square velocity level adjusted for distance
$L_{v\ ref}$	source reference vibration level at 25 feet
m	metre
m^3	cubic metre
mm	millimetre
ms	milliseconds
mm/s	metres per second
MECP	Ontario Ministry of Environment, Conservation and Parks
MNL	mitigation noise level
MRSA	Mine rock storage area
PDA	Project Development Area
PPV	peak particle velocity
PWL	sound power level
RAA	Regional Assessment Area
rms	root mean square
s	second
SLM	sound level meter
TDR	Technical Data Report
the Project	Lynn Lake Gold Project
TMF	Tailings Management Facility
VdB	vibration velocity in decibel scale
W	highest weight of explosives fired per delay
WHO	World Health Organization

1.0 INTRODUCTION

The Lynn Lake Gold Project (LLGP; or "the Project") consists of two primary deposit sites, which are both located near Lynn Lake, Manitoba: The 'Gordon' site and the 'MacLellan' site. Alamos Gold Inc. (Alamos) intends to construct (redevelop), operate and eventually close/reclaim open-pit gold mines at both of these historical mine sites. The Gordon site is located approximately 55 kilometres (km) east of Lynn Lake, Manitoba (by vehicle), and the MacLellan site is located approximately 8 km northeast of Lynn Lake (by vehicle). Lynn Lake is located approximately 820 km northwest of Winnipeg.

This Noise and Vibration Impact Assessment has been completed to fulfill a requirement of the "Guidelines for the Preparation of an Environmental Impact Statement" (2017) pursuant to the *Canada Environmental Assessment Act* (2012) for the LLGP. The assessment provides an overview of the existing conditions in the Project area and identifies the changes in noise and vibration levels at key receptor locations for the Project to determine potential residual and cumulative changes to noise and vibration for the Environmental Impact Statement (EIS).

The noise and vibration modelling focused on two Project phases: construction and operation. Noise and vibration in the decommissioning/closure phase are expected to be similar to, but less than, in the construction phase because the equipment and activities required will be similar in nature but less in quantity. Modelling also focused on the Project noise and vibration effect on humans outside the Project Development Area (PDA). A total of 42 noise receptors were identified outside the PDA. These receptors included Indigenous communities, potential indigenous receptor areas, permanent and seasonal residences, places of worship, recreation area, school, and hospital.

The noise model considered noise emission from mobile and stationery equipment during construction and operation activities at both Gordon site and MacLellan site. Mobile equipment included the trucks moving around the Project area (e.g., haul trucks, loaders, excavators). Stationery equipment included the processing equipment (e.g.., crushers, mills, pumps, compressors).

The vibration model considered mobile equipment induced ground-borne vibration effect on human habitats and structures during the construction phase. In the operation phase, the model considered open pit production blast-induced ground vibration and air blast overpressure effects on human habitats and structures.

This report is presented in eight sections. Section 1 is the introduction and Section 2 examines the local and regional settings, including receptor locations. Section 3 summarizes the regulatory framework used for the modelling. Section 4 presents the baseline conditions and Section 5 explains the model approach. Section 6 presents the modelling results. Concluding remarks are provided in Section 7 and references cited are listed in Section 8.

2.0 ASSESSMENT AREA AND RECEPTORS

2.1 PROJECT DEVELOPMENT AREA (PDA)

The Project Development Area (PDA) encompasses the immediate area in which Project activities and components may occur plus a 30 m buffer and is the anticipated area of direct physical disturbance associated with construction and operation of the Project (i.e., the Project footprint). The PDA includes the access roads, the open pits, mine rock storage areas, overburden stockpiles, and ore stockpiles at the Gordon and MacLellan sites; and the Tailings Management Facility (TMF) and ore milling and processing plant at the MacLellan site. The PDA does not include Provincial Road 391 (PR 391) that connects the Gordon and MacLellan sites. The extent of the PDA at the Gordon site and MacLellan site is shown on Map 1 and Map 2, respectively.

2.2 LOCAL ASSESSMENT AREA (LAA) AND REGIONAL ASSESSMENT AREA (RAA)

The Local Assessment Area (LAA) includes an area extending two kilometres (km) out from the PDA and the section of PR 391 between the Gordon and MacLellan access roads. The LAA is the area Project-specific environmental effects on noise and vibration can be predicted or measured with a reasonable degree of accuracy and confidence.

The Regional Assessment Area (RAA) represents the area within which cumulative effects on noise and vibration effects are likely to occur, depending on the location of other existing, approved, or planned developments. The RAA is defined as an area extending five km out from the PDA and the section of PR 391 between the Gordon and MacLellan access roads.

The extent of the LAA and RAA at the Gordon site and MacLellan site is shown on Map 1 and Map 2, respectively.

The noise modelling domain of 15 km x 25 km is used for the Gordon site. The noise modelling domain of 19 km x 19 km is used for the MacLellan site. The noise model domain includes both the LAA and RAA.

2.3 RECEPTORS

The selection of noise and vibration receptors outside the Project PDA is based on the Health Canada noise guidance. Receptors include:

- Indigenous communities
- Potential indigenous receptor area
- Permanent and seasonal residences
- Places of worship

- Recreation areas
- School
- Hospital.

The noise and vibration receptors for the Gordon site and MacLellan Site are summarized in Table 2-1 and Table 2-2, respectively. These receptors at the Gordon site and MacLellan site are shown on Map 1 and Map 2, respectively.

Note:
[1] This receptor location was a youth camp, but the status is unknown because there were reports of a fire. It is unclear if the camp will be operational in the future

Health Canada noise guidance recommends the assessment of noise impacts such as sleep disturbance on off-duty workers residing in or near the Project area. As a result, the temporary and permanent work camp has been included as additional noise sensitive receptors in the context of sleep disturbance.

3.0 REGULATORY FRAMEWORK

3.1 NOISE

Environmental noise typically varies over time. To account for this variation, a single number descriptor known as the energy equivalent sound level (L_{eq}) is used. It is defined as the steady, continuous sound level over that specified time that has the same acoustic energy as the actual varying sound levels over the same time. The unit for L_{eq} is A-weighted decibel level (dBA). dBA is a logarithmic measurement unit where the recorded sound has been filtered using the “A” frequency weighting scale. A-weighting somewhat mimics the response of the human ear to sounds at different frequencies. Unweighted or linear sound level measurement unit without the A-weighted filter are denoted by dB, dBL, or dBZ.

For a summary of acronyms and additional details on commonly used noise terminology, refer to Appendix A.

3.1.1 Provincial Guideline

The Manitoba Guidelines for Sound Pollution prepared by the Environmental Management Division provides environmental sound level objectives for the assessment of noise in the outdoor environment. The highest desirable level for residential areas is 55 dBA during the daytime (7:00 AM to 10:00 PM) and 45 dBA during the nighttime (10:00 PM to 7:00 AM).

3.1.2 Federal Guidance

Health Canada's Useful Information for Environmental Assessments document (Health Canada 2017) provides noise targets for annoyance, sleep disturbance, and low-frequency noise effects. Health Canada's approach to noise assessment is based on a number of international standards and technical publications. The technical standards and publications referenced in the Health Canada document can be used as guidance for assessments. Noise sensitive receptor locations are based on Health Canada noise guidance as presented in Section 2.3.

3.1.2.1 Annoyance Targets

The Health Canada Noise Guidance (Health Canada 2017) uses daytime or nighttime equivalent sound levels (L_d and L_n, respectively), day-night average sound levels (L_{dn}), adjusted day-night average sound levels ($L_{dn, adjusted}$), and percent highly annoyed (%HA) to quantify noise effects for activities with a duration of more than 12 months.

The daytime sound level (L_d) is a 15-hour time average over the daytime period from 7:00 AM to 10:00 PM. The nighttime sound level (L_n) is a 9-hour time average over the nighttime period from 10:00 PM to 7:00 AM. The day-night average sound level (L_{dn}) is a 24-hour time-averaged L_{eq}, with a 10-dB penalty applied to nighttime hours. The adjusted day-night average sound level ($L_{dn, adjusted}$) is day-night average sound level with adjustments made for certain characteristics of sound such as expectation of "peace and quiet", tonality, or impulsiveness.

Receptors in rural areas could be considered to have a greater expectation of "peace and quiet" (i.e., quiet rural areas) than in urban areas. The Health Canada Noise Guidance considers a "quiet rural area" to be a rural area with L_{dn} due to human-made sounds to be below 45 dBA. A receptor with an existing sound level of 45 dB L_{dn} or less is considered as a quiet rural area. Due to the expected heightened sensitivity to noise, existing levels in quiet rural areas are adjusted by adding 10 dB. This +10-dB adjustment also applies to the predicted Project noise levels in determining percent highly annoyed (%HA). The effect of this +10-dB adjustment in quiet rural areas is to produce a greater change in %HA than would occur with unadjusted noise levels. The exponential relationship between %HA and noise levels produces increasingly larger changes in %HA for equal increases in Project noise, compared to the baseline level.

Impulsive and tonal characteristics of source noise are accounted for in the %HA calculations because their presence can increase annoyance. If the change in %HA is exceeded, effects are considered to be of concern and may require mitigation.

Health Canada Noise Guidance recommends the highest increase for change in %HA is 6.5% at a receptor for Project activities with a duration of more than one year. If the change in %HA exceeds 6.5%, effects are of concern and may require mitigation. Health Canada also recommends mitigation of Project noise if it exceeds L_{dn} of 75 dBA at a receptor, even if the change in %HA does not exceed 6.5%.

For activities less than 12 months, Health Canada noise guidance considers the mitigation noise level (MNL) to assess noise effect. The MNL was used as a target for noise effects related to short-term construction activities such as pile driving. The MNL of 47 dBA (L_{dn}) for a quiet suburban or rural community is applicable. Various correction factors can be applied to the MNL, depending on construction duration, noise source characteristics, and seasonality. The correction factors that can be applied to the basic MNL are as follows:

- Construction activities less than two months, +10 dB L_{dn} correction.
- Negligible tonal or impulsive noise, + 5 dB L_{dn} correction.
- Winter season construction, +5 dB L_{dn} correction.

3.1.2.2 Sleep Disturbance

Health Canada noise guidance references the guidelines and recommendations of the World Health Organization (WHO) Guidelines for Community Noise (WHO 1999) and Night Noise Guidelines for Europe (WHO 2009) regarding sleep disturbance. The WHO (1999) recommends a target for sleep disturbance as being an indoor sound level of no more than 30 dBA L_{eq} for continuous noise during the sleep period.

The indoor sound level is affected by the outdoor-to-indoor sound transmission of a building structure. Health Canada noise guidance recommends that an outdoor-to-indoor sound transmission loss with windows at least partially open is 15 dBA and fully closed windows are assumed to reduce outdoor sound levels by approximately 27 dBA. However, the outdoor-to-indoor sound transmission loss could vary between different building construction for receptors outside the PDA. More recently, the WHO (2009) has published nighttime noise guidelines that are intended to protect the public, including the most vulnerable groups, from adverse health effects associated with sleep disturbance due to nighttime noise. The recommended annual average is 40 dBA L_n outdoors. The outdoor nighttime annual sound level of 40 dBA was used as the sleep disturbance noise target for all receptors outside the PDA in the noise model.

Health Canada noise guidance recommends the assessment of noise impacts such as sleep disturbance on off-duty workers residing in or near the Project area, with consideration of mitigation measures in the design of living quarters for workers to limit noise. As a result, the temporary and permanent work camps were included as noise receptors in the context of sleep disturbance effects. The outdoor-to-indoor sound transmission loss of the work camp can be estimated by the camp construction information. The WHO (1999) indoor sound level of 30 dBA was used as the target for sleep disturbance effects at the work camp.

3.1.2.3 Low Frequency Noise

Sounds with strong low frequency noise (LFN) content may result in noise-induced rattles within buildings, resulting in greater annoyance. As a target for the LFN issue, Health Canada noise guidance recommends that the energy sum of the linear sound levels in the 16, 31.5 and 63-Hz octave bands at a receptor location not exceeding 70 dBL.

3.2 VIBRATION

Manitoba does not have provincial guidelines for vibration. Provincially, the Ontario Ministry of Environment, Conservation, and Park (MECP) provides guidance on blast-related vibration which is referenced herein in absence of Manitoba guidance. Federally, the Health Canada Noise Guidance (Health Canada 2017) provides guidance on blast related vibration.

For non-blast-related construction activities, there is no available Manitoba or federal construction vibration guidance for remote locations or smaller population centers. As published codes and guidance for non-blast-related vibration levels are limited, the United State Federal Transit Administration Transit Noise and Vibration Impact Assessment Manual (FTA 2018) is referenced for ground-borne vibration target.

3.2.1 MECP Guidance

In blasting activity, the explosive energy is intended to break hard rock. However, some energy travels beyond the intended work zone through the ground. The ground vibration level in this model is defined in terms of peak particle velocity (PPV) and is measured in mm/s, representing the highest instantaneous positive or negative peak of the vibration signal. Blast energy that liberates into the atmosphere generates air overpressure. Air overpressure is the additional pressure above normal atmospheric pressure that is generated from a blast and is measured in decibels (dBL).

The MECP Guidelines on Information Required for the Assessment of Blasting Noise and Vibration (MECP 1985) guidance recommends the following vibration targets:

- Standard targets – ground vibration of 12.5 mm/s and air overpressure of 128 dBL.
- Cautionary targets – ground vibration of 10 mm/s and air overpressure of 120 dBL.

The cautionary targets of 10 mm/s and 120 dBL are the most conservative blast-related vibration targets in this assessment. These targets will be applied to all receptors outside the PDA.

3.2.2 Health Canada Guidance

Health Canada only provides threshold for air overpressure effect. The guidance recommends that little or no public annoyance is expected to result from any number of daytime sonic booms per day, if their measured or predicted peak value is below 125-10 log N (dBL), where N is number of blasts per day. For one blast per day, the limit is 125 dBL. At receptor inside the PDA such as the Permanent Work Camp, the Health Canada overpressure target of 125 dBL will be used.

3.2.3 FTA 2018 Guidance

The Federal Transit Administration (FTA) provides guidance on structural damage threshold due to vibration effects from mobile and stationery heavy equipment. Structural damage targets for ground-borne vibration are expressed in terms of PPV levels in mm/s. Structural damage target at a residential building due to ground-borne vibration effect is the PPV of 5 mm/s for non-engineered timber and masonry buildings.

Ground-borne vibration related to human annoyance is related to root mean square (rms) velocity levels, expressed in VdB. The annoyance target for frequent ground-borne vibration is 72 VdB.

4.0 BASELINE CONDITIONS

The baseline conditions for receptors allows a characterization of the interaction between the Project noise and vibration effect and the existing environment.

4.1.1 Noise

An understanding of the baseline noise environment within the Project area is required to assess the effect of noise resulting from the Project.

4.1.1.1 Baseline Noise Survey

A baseline noise field survey in the Project area was conducted in 2015. Details were provided in the "Lynn Lake Gold Project (LLGP): Acoustic Baseline Technical Data Report" (Stantec Consulting Ltd. 2017). Following from a request made by the Canadian Environmental Assessment Agency (now the Impact Assessment Agency of Canada), on account of the passage of time since the completion of the 2015 noise survey, an Acoustic Baseline Validation Report was completed (Stantec 2020), which outlines the validation process for the survey. As there have been no new substantial sources of noise (e.g., commercial, residential or industrial) added to the Town of Lynn Lake or the surrounding area since 2015, the 2015 survey thereby provides an understanding of the acoustic environment in the Project area and the surrounding environment. The baseline data gathered are sufficient to form an understanding of current acoustic conditions, and no additional baseline surveys are required.

The purpose of the noise baseline survey was to quantify the baseline sound levels at noise-sensitive receptors that were close to the Project area to establish baseline conditions against which potential Project effects could be evaluated in the environmental assessment.

Three locations (referred to as NM1, NM2, and NM3) were selected to monitor the existing noise level for five days (Map 1). Location NM1 was at a cottage adjacent to Burge Lake, west of the MacLellan site (NM1). NM2 was located at a remote site south of the Gordon site. NM3 was within the Black Sturgeon Reserve. Map 1 shows noise monitoring locations within the RAA.

Three Type 1 integrating sound level meters (SLMs) meeting the ANSI S1.43-1997 standard were used for measuring ambient noise. The equipment used comprised Brüel and Kjær® 2250 (B&K 2250) Type 1 SLM and Type 4952 outdoor microphone and preamp. Each SLM was enclosed in an individual weather-proof hard case and powered by an external battery for overnight continuous unattended monitoring. The outdoor microphones were set up on a tripod at a height of 1.5 m and connected to the SLM using an extension cable. Each SLM collected the following data:

- One-minute integrated A-weighted overall sound levels ($L_{eq,\ 1min}$) in dBA.
- One-minute integrated linear sound levels at One Third Octave Band Frequency (L_{eq}) in dB.
- Continuous audio sound recording for the duration of the field survey.

Each SLM was laboratory-calibrated within the previous 24 months as recommended in other provincial noise guidelines (AUC 2019 and BC OGC 2018). A portable field calibrator, Brüel and Kjær® Type 4231, was used to calibrate the SLMs immediately before and after each measurement series and after changes in equipment conditions (e.g., cable or battery replacement).

The data from the field study were analyzed to identify noise sources for each monitoring period such as natural sounds and local activities. Data that were not representative of normal site activity (i.e. animals and birds interfering with SLM, Stantec staff) or non-representative weather conditions (i.e. rain and high wind speed more than 15 km/hr) were isolated from the data set prior to the calculation of averages or other statistical values. Filtered hourly ($L_{eq,\ 1hr}$), daytime (L_d), and nighttime (L_n) equivalent sound levels were then calculated for the measurement period. There were 92, 85, and 70 hours of monitoring at NM1, NM2, and NM3, respectively.

Measured data that are not typical of ambient sound levels were excluded from the measurements. Invalid data generally includes periods with non-representative weather conditions (e.g., rain precipitation and high wind), which are typically associated with excessive sound level recordings. This approach of isolating non-representative events is considered reasonable and results in a lower baseline sound level or quieter existing acoustic environments. Consistent with environmental assessment principles, this is a conservative approach.

The average daytime and nighttime sound level (L_d and L_n) monitoring results are summarized in Table 4-1.

Table 4-1 Daytime and Nighttime Sound Level at Baseline Monitoring Locations

Monitoring Location	Description	Daytime Sound Level, L_d (dBA)	Nighttime Sound Level, L_n (dBA)	Day-Night Average Sound Level, L_{dn} (dBA)
NM1	Burge Lake Provincial Park	40.6	35.2	42.9
NM2	Gordon Site	34.3	33.4	40.0
NM3	Black Sturgeon Reserve	39.4	37.9	44.6

Location NM1 is representative of a rural area with dominant noise sources from residents' activities, local traffic, watersport and recreational activities, occasional aircraft flyovers, vegetation rustling, wildlife, insects, and water ripple noise. The average L_d and L_n values are 40.6 dBA and 35.2 dBA, respectively.

The L_d values are higher than the L_n values. This is due to residential, watersport, and recreational activities occurring at Burge Lake Provincial Park, which occur mostly during the daytime periods. During the nighttime period, the acoustic environment is quieter, characterized by occasional wildlife calling and the dawn chorus around sunrise. The NM1 results provide a baseline acoustic environment for the residences along the lake shores in Burge Lake Provincial Park during the summer season.

Location NM2 is representative of a remote area with limited human activity. The dominant noise sources observed during the field survey at NM2 included wildlife, birds, insects, occasional aircraft flyovers, vegetation rustling, and wind noise. The average daytime L_d and nighttime L_n values are 34.3 dBA and 33.4 dBA, respectively. There was limited human activity recorded during the measurement period other than the Stantec study team personnel setting up the acoustic environment monitoring equipment and two vehicle pass-by events, that were isolated from the L_d and L_n calculations. Therefore, NM2 results provide a baseline characterization of the acoustic environment in remote areas within the RAA during the summer season.

Location NM3 is representative of a sparsely populated area with frequent noise events from the residents, children, domestic animals, birds, and insects. The average L_d and L_n values are 39.4 dBA and 37.9 dBA, respectively. The acoustic environment is dominated by residential and recreational activities during the daytime and earlier part of the nighttime period (due to longer daylight hours), occasional dog barking, wildlife calling, and dawn bird chorus during sunrise. The NM3 results provide a baseline characterization of the acoustic environment for the residential area within the Black Sturgeon Reserve during the summer season.

4.1.1.2 Estimated Baseline Sound Levels

While the standard approach for baseline sound determinations is direct measurement, there may be situations where baseline measurement data are not available. Health Canada Noise Guidance (Health Canada 2017) provide alternative approaches to estimating baseline levels based on qualitative descriptions and population density, as shown in Table 4-2.

Table 4-2 Health Canada Estimate Baseline Sound Levels

Community Type	Population Density (person per square km)	Estimated Baseline Sound Level, L_{dn} (dBA)
Quiet Rural - dwelling units more than 500 m from heavily travelled roads and/or rail lines and not subject to frequent aircraft flyovers	28	≤ 45
Quiet Suburban Residential - remote from large cities, industrial activity and trucking	249	48 to 52
Normal Suburban Residential - not immediately adjacent to heavily travelled roads and industrial areas	791	53 to 57

4.1.1.3 Baseline Sound Level

The Health Canada noise guidance recognizes that both measurements and estimates are acceptable methods in establishing the baseline sound levels for receptors. The baseline sound level at the receptors can be estimated from two data sources.

The first data source uses the measurement results from the baseline monitoring program. The baseline sound level at some of the receptors is based on the results from one of the three monitoring locations, due to the proximity to the measurement location or similar acoustic environment (i.e., remote locations). The results at the three monitoring locations (NM1, NM2, and NM3) can be used to represent the existing sound level at some of the receptors. The baseline sound level at the recreation lot, youth camp, and park vacation home near Burge Lake are represented by the monitoring results from NM1. Potential indigenous receptors (e.g., trap lines, trapping areas, and fishing camps), trapper cabin, remote cottages, and recreation lot are in a remote area. The baseline sound level at these locations are represented by the monitoring results from NM2. Receptor locations within the Black Sturgeon Reserve are represented by monitoring results from NM3.

The second data source uses the estimated baseline sound level for different communities recommended in the Health Canada noise guidance for a receptor location. Baseline sound levels at receptors located in the community of Lynn Lake were based on levels advised in Health Canada noise guidance for quiet rural communities (i.e., population density of 28 per square km). The Health Canada quiet rural community baseline sound level is 45 dBA L_d and 35 dBA L_n (or L_{dn} of 45 dBA). This actual baseline sound level is likely to be higher because the population density at Lynn Lake is more than 28 per square km. However, the quieter baseline sound level is considered a more conservative approach.

The baseline sound level at each receptor is listed in Table 4-3 and Table 4-4 for the Gordon site and MacLellan site, respectively. The baseline sound levels selected for each receptor represents the existing acoustic environment, based on available information from the noise survey and Health Canada Noise Guidance (Health Canada 2017). These values were used in the assessment of %HA target for annoyance.

Table 4-3 Receptor Baseline Sound Level – Gordon Site

Receptor ID	Description	Daytime Sound Level, L_d (dBA)	Nighttime Sound Level, L_{dn} (dBA)	Day-Night Sound Level, L_{dn} (dBA)	Based on Monitoring Location

Note:

[1] Baseline sound levels at receptors located in the community of Lynn Lake were based on levels advised in Health Canada noise guidance for quiet rural communities

[2] This receptor location was a youth camp, but the status is unknown because there were reports of a fire. It is unclear if the camp will be operational in the future

4.1.2 Vibration

In contrast to audible noise, the background environmental ground-borne vibration levels in an outdoor rural area without local human activities is typically below the threshold of human perception (FTA 2018). The typical threshold of human perception of ground vibration is 0.5 mm/s PPV (ISEE 2011); however, the perceptibility threshold varies from person to person. In an urban and suburban environment, a person may be subjected to a wide range of vibration effects depending on the location, time of the day, proximity to day-to-day vibration sources (e.g., vehicle, train, construction activities).

The FTA noise and vibration guideline (FTA 2018) recommends that background vibration velocity level in residences is usually 50 VdB or lower, and the threshold of perception for humans is approximately 65 VdB.

Vibration targets are applicable to individual events or occurrences only and do not consider existing vibration levels. The vibration model is therefore based on comparing the effects from Project only events (e.g., blasting) to the targets. The effect from background vibration level or cumulative vibration level from another event is typically not included. Therefore, a vibration baseline study for the existing condition was not performed.

5.0 MODEL APPROACH

The following list outlines the noise model approach. Stantec conducted the following tasks:

1. Conducted noise baseline study at selected locations.
2. Defined the LAA, RAA, and receptors.
3. Established the baseline sound level at the noise receptors.
4. Identified modelling scenarios that will reflect worst case construction and operation in terms of noise emissions.
5. Determined noise emission sources from Project construction and operation activities.
6. Characterized these sources by their sound power levels (PWLs) using manufacturer’s data, acceptable theoretical calculation methods, or similar equipment noise data from an archived database of measurements.
7. Developed an acoustic model for each modelling scenario.
8. Established the sound levels within the LAA and RAA, and at receptors by applying the emission sources in noise models for construction and operation phases.
9. Assessed compliance of the Project by comparing the modelled results to the applicable noise targets (i.e., Health Canada Noise Guidance and Manitoba Noise Guidelines).

10. If the modelled results are in compliance with applicable criteria, the noise effect is considered to be acceptable. Otherwise, mitigation measures are identified by re-modelling to manage the noise effects.

The following list outlines the vibration model approach:

1. Defined the LAA, RAA, and receptors.
2. Predicted the ground-borne vibration effect at the receptors due to construction activities
3. Predicted the air overpressure and ground-borne vibration effects at the receptors due to in-pit blasting
4. Assessed compliance of the Project by comparing the modelled results to the applicable vibration targets (i.e., FTA, Health Canada, and MECP).
5. If the results are in compliance with applicable criteria, the vibration effect is considered to be acceptable. Otherwise, mitigation measures are identified by re-modelling to manage the vibration effects.

5.1 NOISE

5.1.1 Modelling

Noise modelling used the latest version of the Cadna/A® software (DataKustik 2019), which incorporates International Organization for Standardization (ISO) Standard 9613 (ISO 1993, 1996) algorithms. ISO 9613 standards are commonly used by acoustic practitioners for modelling sound propagation and are accepted by Health Canada. The Cadna/A® software model accounts for the following factors:

- Geometric spreading.
- Screening effects.
- Atmospheric absorption.
- Source size, location, and elevation.
- Mild downwind from the Project to the dwelling(s) and or temperature inversion condition.
- Source directivity.

Table 5-1 lists the modelling parameters used in the model.

Table 5-1 Noise Modelling Software Parameters

Item	Model Parameters	Model Setting
1	Temperature	10°C
2	Relative humidity	70%
3	Wind speed	Downwind condition, wind speed of 1 to 5 m/s
4	Noise source	Refer to Section 5.1.2, Section 5.1.3, and Appendix C
7	Noise Propagation Standard	ISO 9613
8	Ground conditions and attenuation factor	• Ground absorption (G) of 0.5 for the Project site and surrounding area with predominantly soil with short grass • Ground absorption (G) of 0 for lake areas
9	Terrain Parameters (terrain resolution)	Ground terrain incorporated in model
10	Reflection parameters	1 order reflection

5.1.2 Construction

Based on the review of the mine plan and equipment list, the time period from the second quarter of Year -2 to the fourth quarter of Year -1 was chosen for modelling of the construction phase at the Gordon site and the MacLellan site because it represents the worst-case scenario of equipment usage during activities such as bulk earth work, pre-production mining activities, and piling activities for the bridge construction over the Keewatin River (MacLellan site) and old diversion channel (Gordon site).

The Project construction phase noise emissions were established using the following information sources:

- Equipment lists, design data, equipment noise ratings provided by Alamos, Q'Pit Inc., and Ausenco Engineering Canada Inc. (Ausenco).
- Measurement data of similar equipment from Stantec acoustic database
- Equipment specifications and referenced formula from acoustic literature (Crocker 2007, Bies and Hansen 2004)
- Publication that provides reference sound power levels and sound pressure levels for common construction equipment (DEFRA 2005).

5.1.2.1 Processing Plant

There is one processing plant at the MacLellan site and no processing plant at the Gordan site. The processing plant construction includes equipment presented in Table 5-2. Details of the equipment sound power levels in full octave band frequency are presented in Appendix B.

Table 5-2 Processing Plant Construction Equipment Summary

Item	Description	Quantity	Sound Power Level (dBA) Per Unit
1	John Deere 700K Dozer	1	108
2	John Deere 850K Dozer	3	111
3	Cat D8 Dozer	2	110

29	Flushing Equipment	1	91
30	Hammer (John Deere 400 Excavator)	1	115
31	C-Can Buses	5	104

The construction phase noise emissions for the processing plant are based on the following assumptions:

- Worst case scenario is based on the period between Q2 Year -2 and Q4 Year -1.

- Equipment operates 10 hours (6 hours daytime and 4 hours nighttime) during a 24-hour period.
- Equipment operates at 100% capacity.
- Pile driving activities occur at the Keewatin River bridge (MacLellan site) and the old diversion channel (Gordon site) during daytime (7:00 to 22:00).
- Piling activities were assumed to be less than 12 months.
- Active piling is assumed to be 30% of the equipment operating time, with a 12 dB tonality penalty added to noise emissions.
- Back-up alarms are assumed to be 20% of the equipment operating time, with a 5 dB tonality penalty added to noise emissions.

5.1.2.2 Tailing Management Facility

There is one TMF at the MacLellan site and no TMF at the Gordon site. The construction of the TMF includes the equipment presented in Table 5-3. Details of the equipment sound power levels in full octave band frequency are presented in Appendix B.

Table 5-3 Tailing Management Facility Construction Equipment Summary

Item	Description	Quantity	Sound Power Level (dBA) per unit
1	Cat D6 Dozer	4	108
2	Cat D7 Dozer	1	108

26	Generator 25 kW	2	98
27	Generator 50 kW	2	86
28	Light Plant	1	89
29	Compressor	5	104

The construction phase noise emissions for the TMF are based on the following assumptions:

- TMF construction activities occur during the worst-case scenario within the TMF area at MacLellan site.
- Equipment operates 10 hours (6 hours daytime and 4 hours nighttime) during a 24-hour period.
- Equipment operates at 100% capacity.
- Back-up alarms are assumed to be 20% of equipment operating time, with a 5 dB tonality penalty added to noise emissions.

5.1.2.3 Pre-Production Equipment

Pre-production activities is not related to the construction phase of the Project; however, the activities will occur during the time period for the processing plant and TMF construction. Therefore, the pre-production noise emission is including in the construction phase modelling. The pre-production equipment for the Gordon site includes the equipment presented in Table 5-4. The pre-production equipment for the MacLellan site includes the equipment presented in Table 5-5. Details of the equipment sound power level in full octave band frequency is presented in Appendix B.

Table 5-4 Pre-Production Equipment Summary – Gordon Site

33	Diesel Light Commercial Pump Portable 8-Inch Dewatering Pump	1	99
34	Diesel Truck Mine Pickup Truck	10	106

The pre-production noise emissions are based on the following assumptions:

- Mobile equipment operates 20 hours (12.5 hours daytime and 7.5 hours nighttime) during a 24-hour period.
- Equipment operates at 100% capacity.
- Stationery equipment (i.e., Temporary Crusher) operates at 100% capacity continuously during 24-hour period.
- Back-up alarms are assumed to be 20% of equipment operating time, with a 5 dB tonality penalty added to noise emissions.

5.1.2.4 Haul Road Traffic

The pre-production haul road traffic within the Gordon site and MacLellan site is presented in Table 5-6 and Table 5-7, respectively. The hourly traffic volume is based on the annual traffic volume. The annual traffic volume is based on annual quantities of transferred material divided by the payload capacity of the haul truck. The annual traffic volume is divided by the actual operating hours per year to estimate the average hourly truck traffic count usage. Therefore, the traffic volume per hour presented in the table is not a round number due to the averaging calculation. Details of the equipment sound power level in full octave band frequency are presented in Appendix B.

Table 5-6 Haul Road Traffic Summary – Gordon Site

Item	Description	Volume (Trucks/hr)	Sound Power Level [1] (dBA)
1	Pit to Ore Stockpile (Articulated Truck 144 Ton)	1.0	121
2	Construction to Waste Area (Articulated Truck 65 Ton)	1.0	119
3	Pit to Waste Area (Articulated Truck 144 Ton)	1.4	121
4	Pit to Overburden (Articulated Truck 40 Ton)	1.3	118

Note:
[1] Represent sound power level per unit of mobile equipment

Table 5-7 Haul Road Traffic Summary – MacLellan Site

Item	Description	Volume (Trucks/hr)	Sound Power Level [1] (dBA)
1	Plant to Topsoil (Articulated Truck 40 Ton)	4.3	118
2	Plant to Waste (Articulated Truck 65 Ton)	2.1	119
3	Tailing to Waste (Articulated Truck 40 Ton)	3.5	118
4	Pit to Overburden (Articulated Truck 40 Ton)	3.4	118
5	Pit to Waste Rock Stockpile (Articulated Truck 144 Ton)	2.7	121
6	Pit to Ore (Articulated Truck 40 Ton)	2.3	118
7	Pit to Crusher (Articulated Truck 40 Ton)	13.9	118
Note: [1] Represents sound power level per unit of mobile equipment			

The haul road traffic noise emission is based on the following assumptions:

- Equipment operates 24 hours continuously.
- Equipment operates at 100% capacity.
- Highest haul road traffic volumes were used.

5.1.2.5 Access Road

The construction phase access road traffic for Gordon site and MacLellan site is presented in Table 5-8 and Table 5-9, respectively. The traffic volume is based on truck frequency information provided by Ausenco and conservative assumptions made for heavy trucks, pickup trucks, and crew buses.

Table 5-8 Access Road Traffic Summary – Gordon Site

Item	Description	Volume (Trucks/hr)
1	Access Road Traffic	2

Table 5-9 Access Road Traffic Summary – MacLellan Site

Item	Description	Volume (Trucks/hr)
1	Access Road Traffic	6

The access road traffic noise emission is based on the following assumptions:

- Equipment operates 24 hours continuously.
- Equipment operates at 100% capacity.

- Highest access road traffic volumes were used.

5.1.2.6 PR 391

The Project related construction phase traffic along PR 391 between Gordon site and MacLellan site is presented in Table 5-10. The traffic volume is based on truck frequency information provided by Ausenco and conservative assumptions made for mixer trucks, fuel trucks, and delivery trucks.

Table 5-10 PR 391 Construction Traffic Summary

Item	Description	Volume (Trucks/hr)
1	PR 391 Traffic	2

The PR 391 road traffic noise emission is based on the following assumptions:

- Equipment operates 24 hours per day continuously.
- Equipment operates at 100% capacity.
- Highest PR 391 road traffic volumes were used.

5.1.3 Operation

Based on the review of the mine plan and equipment list, the operation phase scenario that was considered representative of the worst-cases for noise emissions were modeled; Year 2 of the Gordon site operation and Year 7 of the MacLellan site operation were chosen because they represent the production year with highest production rates, respectively. This is based on the quantity of the equipment fleet, the haulage lengths, and the total amount of material moved.

The Project operation phase noise emissions were established using the following information sources:

- Equipment lists, design data, equipment noise ratings provided by Alamos, Q'Pit Inc., and Ausenco.
- Measurement data of similar equipment from Stantec acoustic database.
- Equipment specifications and referenced formula from acoustic literature (Crocker 2007, Bies and Hansen 2004).
- Publication that provides reference sound power levels and sound pressure levels for common construction equipment (DEFRA 2005).

5.1.3.1 Processing Plant

The noise model of the processing facility at MacLellan site considers the full built-out phase (i.e., all equipment in operation). There is no processing facility at Gordon site. The facility will operate continuously during a 24-hour period. The plant facility sound power levels are based on a combination of theoretical calculations and past project experiences for similar facilities. The major components of the plant facility are listed as follows:

- Primary crusher building
- Secondary crusher building
- Cover stockpile
- Mill building
- Reagent building
- Gold room
- Oxygen plant
- Conveyors
- Dust collectors
- HVAC units
- Water pump stations.

Table 5-11 to Table 5-17 summarize the noise emission level for indoor equipment and outdoor HVAC equipment associated with different buildings. Noise attenuation effects due to roof and walls sound transmission loss is considered for the indoor equipment in the noise model. Table 5-18 summarizes the noise emission of outdoor equipment that is not enclosed within a building.

Details of the equipment sound power levels in full octave band frequency are presented in Appendix B.

5.1.3.2 Mining Equipment

The noise model of mining equipment during the operation phase include primary equipment, support equipment, and haul road traffic. The primary equipment is used mainly in the Gordon site open pit and the MacLellan site open pit and haul roads. The support equipment is used in the open pits, processing plant, and different areas within the Project boundary. The haul road traffic includes the haul truck and other mobile equipment travelling between different areas.

Primary Equipment

The primary equipment for Gordon site and MacLellan site is presented in Table 5-19 and Table 5-20, respectively. Details of the equipment sound power level in full octave band frequency is presented in Appendix B.

Table 5-19 Primary Equipment Summary – Gordon Site

20	Crawler Dozer 264 kW	1	109

The primary equipment noise emissions are based on the following assumptions:

- Mobile equipment operates 20 hours (12.5 hours daytime and 7.5 hours nighttime) during a 24-hour period.
- Equipment operates at 100% capacity
- Back-up alarms are assumed to on 20% of equipment operating time, and 5 dB tonality penalty added to noise emissions.

Support Equipment

The support equipment for Gordon site and MacLellan site is presented in Table 5-21 and Table 5-22, respectively. Details of the equipment sound power level in full octave band frequency is presented in Appendix B.

Table 5-21 Support Equipment Summary – Gordon Site

Item	Description	Quantity	Sound Power Level (dBA) per unit
1	Rough-Terrain Crane 110 Ton	1	94
2	Hydraulic Excavator 36 Ton	1	103
3	On-Highway Class 8 Dump Truck	1	106
4	Heavy-Duty Light Tower	12	89
5	Flameless Air Mobile Heater	1	91
6	Portable Dewatering Pump (4-Inch)	1	95
7	Portable Dewatering Pump (8-Inch)	1	99
8	Dewatering Pump	2	99
9	Lift Truck/Flatbed	1	119

Table 5-22 Support Equipment Summary – MacLellan Site

Item	Description	Quantity	Sound Power Level (dBA) per unit
1	Rough-Terrain Crane 110 Ton	2	94
2	Hydraulic Excavator 36 Ton	1	103
3	Skid-Steer Loader	1	95
4	Portable Air Compressor (5-6 m^3)	1	104
5	Flameless Air Mobile Heater	1	91
6	Trailer-Mounted Pressure Washer	1	101
7	Portable Dewatering Pump (4-Inch)	1	95
8	Portable Dewatering Pump (8-Inch)	1	99
9	Dewatering Pump	3	99
10	Heavy-Duty Light Tower	28	89
11	Lift Truck/Flatbed	1	119

The support equipment noise emissions are based on the following assumptions:

- Mobile equipment operates 20 hours (12.5 hours daytime and 7.5 hours nighttime) during a 24-hour period.
- Equipment operates at 100% capacity.
- Stationery equipment (i.e., pumps) operates at 100% capacity continuously during a 24-hour period.

Haul Road Traffic

The operation phase haul road traffic within the Gordon site and MacLellan site is presented in Table 5-23 and Table 5-24, respectively. The annual traffic volume is based on annual quantities of transferred material divided by the payload capacity of the haul truck. The annual traffic volume is divided by the actual operating hours per year to estimate the average hourly truck traffic count usage.

Details of the equipment sound power level in full octave band frequency is presented in Appendix B.

Table 5-23 Haul Road Traffic Summary – Gordon Site

Item	Description	Volume (Trucks/hr)	Sound Power Level [1] (dBA)
1	Pit Area to Overburden (Articulated Truck 30 Ton)	3	108
2	Haul Road from Open Pit to Waste Rock Stockpile (Komatsu Haul Truck 136 Ton)	21	121
3	Haul Road from Open Pit to Low Grade Ore Stockpile (Komatsu Haul Truck 136 Ton)	4	121
4	Haul Road in Open Pit (Komatsu Haul Truck 136 Ton)	25	121

Note:
[1] Represent sound power level per unit of mobile equipment

Table 5-24 Haul Road Traffic Summary – MacLellan Site

Item	Description	Volume (Trucks/hr)	Sound Power Level [1] (dBA)
1	Haul Road in Open Pit (Komatsu Haul Truck 136 Ton)	44	121
2	Haul Road from Ore Stockpile to Process Plant (Articulated Truck 30 Ton)	13	108
3	Haul Road from Open Pit to Waste Rock Stockpile (Komatsu Haul Truck 136 Ton)	38	121
4	Haul Road from Open Pit to Low Grade Ore Stockpile (Komatsu Haul Truck 136 Ton)	1	121
7	Haul Road from Open Pit to Overburden Stockpile (Articulated Truck 30 Ton)	6	108
8	Haul Road from Open Pit to Mill (Komatsu Haul Truck 136 Ton)	4	121

Note:
[1] Represent sound power level per unit of mobile equipment

The haul road traffic noise emission is based on the following assumptions:

- Equipment operates 24 hours continuously.
- Equipment operates at 100% capacity.
- Highest haul road traffic volumes were used.

5.1.3.3 Access Road

The access road traffic for Gordon site and MacLellan site is presented in Table 5-25 and Table 5-26, respectively. The truck traffic is based on truck frequency information provided by Ausenco and conservative assumptions made for heavy trucks, pickup trucks, and crew buses.

Table 5-25 Access Road Traffic Summary – Gordon Site

Item	Description	Volume (Trucks/hr)
1	Access Road Traffic	12

Table 5-26 Access Road Traffic Summary – MacLellan Site

Item	Description	Volume (Trucks/hr)
1	Access Road Traffic	12

The access road traffic noise emission is based on the following assumptions:

- Equipment operates 24 hours continuously.
- Equipment operates at 100% capacity.
- Highest access road traffic volumes were used.

5.1.3.4 PR 391

The Project related operation phase PR 391 traffic between Gordon site and MacLellan site is presented in Table 5-27. The traffic volume is based on truck frequency information provided by Ausenco and conservative assumptions made for haul trucks, delivery trucks, and fuel trucks.

Table 5-27 PR 391 Operation Traffic Summary

Item	Description	Volume (Trucks/hr)
1	PR 391 Traffic	12

The PR 391 road traffic noise emission is based on the following assumptions:

- Equipment operates 24 hours per day continuously.
- Equipment operates at 100% capacity.
- Highest PR 391 traffic volumes were used.

5.1.4 Decommissioning/Closure

The noise effects model focused on activities during the construction and operation phase. The quantity of equipment required for the decommissioning/closure phase is expected to be below that required for the construction and operation phases. Noise emissions during decommissioning/closure activities are expected to be similar to, but less than, in the construction phase, and as such noise effects will be less than those of construction. Accordingly, quantitative noise modelling of decommissioning/closure phase was not conducted.

5.2 VIBRATION

5.2.1 Modelling

The FTA 2018 guidance recommends the vibration assessment for building damage be performed for each piece of equipment individually using PPV as the measurable parameter. The vibration level at a receptor is predicted by using the reference vibration level (PPV_{ref}) for each piece of equipment at a reference distance of 7.62 m and the distance from equipment to receptor, as described in Equation 1 below.

$$PPV = PPV_{ref} \times (7.62/D)^{1.5} \qquad \text{Equation 1}$$

Where:

PPV = Peak particle velocity at the receptor (mm/s)
PPV_{ref} = the source reference vibration level at 7.62 m (mm/s)
D = Distance from equipment to receptor (m).

The FTA 2018 guidance recommends that annoyance due to vibration be performed for each piece of equipment individually. The vibration level at a receptor is predicted by using the vibration source level (L_{vref}) for each piece of equipment at a reference distance of 7.62 m and the distance from equipment to receptor, as described in Equation 2 below.

$$L_{v,distance} = L_{vref} - 30\ LOG\ (D/7.62) \qquad \text{Equation 2}$$

Where:

$L_{v,distance}$ = the root mean square velocity level adjusted for distance (VdB)
L_{vref} = the source reference vibration level at 7.62 m (VdB)
D = Distance from equipment to receptor (m).

In the vibration assessment of blasted related activities from the open pits during operation, equations commonly used and accepted by the industry were used to predict the blast-induced ground vibration and air level (ISEE 2011).

Ground vibration level related to blast activities is defined in terms of PPV and is measured in mm/s, representing the highest instantaneous positive or negative peak of the vibration signal. A commonly used and accepted equation from the International Society of Explosives Engineers (ISEE) technical literature Blasters’ Handbook (ISEE 2011) was used to predict vibration levels for a coal mine, as presented in Equation 3.

$$PPV = 3330(D/W^{1/2})^{-1.52} \qquad \text{Equation 3}$$

Where:

PPV = Peak particle velocity at a receptor (mm/s).
D = Distance from the blast to nearest inhabited residential dwelling (m).
W = Highest weight of explosives fired per delay (kg).

During blasting, blast energy that liberates into the atmosphere generates air overpressure. Air overpressure is the additional pressure above normal atmospheric pressure that is generated from a blast and is measured in decibels (dBL). Air overpressure often feels like a gust of wind by a receptor as a confined blast will generally result in an inaudible air overpressure. Equation 4 is commonly accepted by the industry to predict air overpressure levels at a point of concern was developed by the Blasters’ Handbook (ISEE 2011) for a metal mine.

$$\text{Air overpressure} = 14.3\ (D/W^{1/3})^{-0.71}\ [\text{Pa}] \qquad \text{Equation 4}$$

Where:

Air overpressure in Pascals
C = Confinement constant
D = Distance from blast to point of concern (m)
W = Weight of explosives per delay (kg).

The overpressure can be converted from Pascal (Pa) to dBL Equation 5 presented below.

$$\text{Air overpressure \{dBL\}} = 20\ \text{LOG}\ (\text{Air overpressure \{Pa\}}/2 \times 10^{-5}) \qquad \text{Equation 5}$$

The following assumptions were used in the blast-related vibration model:

- Vibration prediction used a conservative method with the highest explosive charge weight. The actual blast charges could be lower.
- Blast-related vibration prediction was based on the shortest distance between receptor and the pit boundary.

5.2.2 Construction

During the construction phase, heavy equipment such as excavators, compactors, piling equipment, and haul trucks will be used. The ground-borne vibration effect due to high impact piling equipment, excavator, compactor, drilling, and large bulldozer were assessed at receptors closest to the construction activities. These pieces of equipment were selected in this model because they typically produce higher vibration levels than other construction equipment. Based values recommended in the FTA noise and vibration guideline (FTA 2018), the construction equipment reference vibration level in PPV_{ref} and $L_{v,ref}$ are summarized in Table 5-28.

Table 5-28 Construction Equipment Reference Vibration Level at 25 feet or 7.62 m

Construction Equipment	PPV_{ref} (mm/s)	$L_{v,ref}$ (VdB)
Vibratory Roller	5.33	94
Bulldozer	2.26	87
Drilling	2.26	87
Clam Shovel	5.13	94
Impact Piling	38.56	112

5.2.3 Operation

During the operation phase, the primary vibration effects are ground vibration and air overpressure due to blasting activities within the open pit at the Gordon site or the MacLellan site. Given the same distance from a blast to the receptor, the primary factor affecting vibration is the explosive charge per delay. The highest explosive charge specification in the blast design is 208 kg per hole per delay for both the Gordon and MacLellan sites. However, the explosive charge could be reduced during operation due to site conditions.

The closest receptors to the Gordon site open pit are receptors ID 76 and ID 73 at the approximate distance of 1.4 km and 2.2 km, respectively. Outside the PDA, the closest receptor ID 86 is approximately 2.4 km from the MacLellan site open pit. All three receptors are First Nation trap lines or trapping areas. Inside the PDA, the closest receptor is the permanent work camp located approximately 800 m from the MacLellan pit.

5.2.4 Decommissioning/Closure

The vibration effects model focused on activities during the construction and operation phases. The quantity of equipment required for the decommissioning/closure phase is expected to be below the requirement for the construction and operation phases, and activities such as blasting, or pile driving, will not be conducted during decommissioning. Vibration effects during decommissioning/closure activities are expected to be less than the construction phase. Accordingly, quantitative vibration model of decommissioning/closure phase was not included.

5.3 PREDICTION CONFIDENCE

Overall, accuracy of predictions for the noise model depends on several factors, including the accuracy of the Project design information, noise source data, and the sound propagation algorithm. The latest Project design information available at the time of this model was used. The sound power levels of the noise sources were established with field measurements of similar equipment or vendor sound emission data, where available. Acoustic models can be revised (if necessary) when final design information is available.

The Cadna/A model predicts outdoor noise in accordance with ISO 9613. The ISO 9613 sound propagation algorithms have a published accuracy of ± 3 dB over source receiver distances between 100 m and 1,000 m. The accuracy for distances up to or over 1.5 km is not stated. The ISO 9613 model also produces results representative of meteorological conditions enhancing sound propagation (e.g., downwind and temperature inversion conditions). These conditions do not occur all the time; therefore, model predictions are expected to be conservative.

To account for the level of uncertainty in the noise predictions, conservative assumptions regarding the Project have been made. These include the assumptions that downwind conditions exist 100% of the time and that the maximum number of equipment operates at rated capacity for each scenario assessed.

Prediction method for blast-related ground-borne vibration are based on upper bound equations. Upper bound equations will generally estimate the highest potential vibration level with at least 95% confidence. Prediction method for blast-related overpressure levels are based on best fit equation. Statistically the best fit equations are meant to estimate the expected air overpressure level. The equations are useful for blasts that are well designed and implemented properly in the field.

Confidence in the blast vibration predictions is high, since the analytical approach and methodology used in this model have been tested and verified in many blast audits worldwide. Confidence in the vibration predictions during construction phase is high because the model was based on methods commonly accepted by the industry.

6.1.3 Mitigation Measures

Mitigation measures are implemented as part of the design to reduce potential noise effects during the construction and operation phases. The mitigation measures are applicable to both the Gordon and MacLellan sites.

- Large stationary machinery (i.e., crushers) will be located inside buildings.
- Fully enclosed conveyor between buildings in processing plant.
- Roads designed to reduce haul distances.
- Large transportation trucks will be used to reduce the number of trips.
- Mobile equipment will have exhaust mufflers.
- Work camp building wall and roof will be noise insulated panel.
- Work camp building will include air conditioning system such that double pane windows and insulated doors can be closed during the summer season.
- Reduce heavy fleets idling when not operating.

The operational sound levels listed in the Appendix B are the estimated equipment sound power levels used in the acoustic modelling; it is assumed that these acoustical specifications are achievable by the suppliers. If the sound power level cannot be achieved, additional mitigation measures may be required.

6.1.4 Comparison to Regulatory Framework

6.1.4.1 Manitoba

During the construction phase the predicted Project L_d and L_n sound levels (see Table 6-1, Table 6-2, Table 6-3, and Table 6-4) at all residential receptors are below the Manitoba noise guideline target of 55 dBA daytime and 45 dBA nighttime. During the operation phase the predicted Project L_d and L_n sound levels (see Table 6-5 and Table 6-6) at all residential receptors are below the Manitoba noise guideline target of 55 dBA daytime and 45 dBA nighttime.

6.1.4.2 Health Canada Change in Percent Highly Annoyed and Mitigated Noise Level

For the construction and operation phases, change in %HA associated with the Project is compared with the threshold of 6.5% advised by Health Canada. The change is %HA at a receptor is based on the difference between the baseline %HA and total (Project and Baseline) %HA.

The %HA is determined from the adjusted baseline sound level or the adjusted total sound level, based on an equation from the Health Canada guidance. The adjusted baseline sound level and adjusted total sound level sound level is calculated by adding the 10 dB “peace and quiet” adjustment to the baseline sound level (Section 4.1.1.3) and total sound level at a receptor. The total sound level is the combined noise effect of the baseline sound level and project sound level (see Sections 6.1.1 and 6.1.2). A detail sample calculation of the change in %HA at a receptor is presented in Appendix C.

The changes in %HA associated with the Project construction phase at Gordon site and MacLellan site are summarized in Table 6-7 and Table 6-8, respectively. The changed in %HA results are compared to the target for change in %HA of 6.5% advised in the Health Canada noise guidance. The changes in %HA at all receptors are below the 6.5% target for the construction phase. The results indicate compliance with the Health Canada guidance.

During pile driving activities with a duration of less than 12 months, the MNL was used as a target for noise effects related to short-term construction activities. The MNL of 47 dBA (L_{dn}) for a quiet suburban or rural community is applicable. Table 6-2 summarizes the predicted sound level for the receptors during pile driving activities for closing off the old diversion channel north of the Gordan open pit. Table 6-4 summarizes the predicted sound level for the receptors during pile driving activities at the Keewatin River bridge at the MacLellan site. The predicted L_{dn} levels at all receptors are below the target of 47 dBA.

Table 6-7 Construction Phase - Change in %HA – Gordon Site

Note:

[1] The + 10 dB "peace and quiet" adjustment is included

The changes in %HA associated with the Project operation phase at Gordon site and MacLellan site are summarized in Table 6-9 and Table 6-10, respectively. The change in %HA results are compared to the target for change in %HA of 6.5% advised in the Health Canada noise guidance. The changes in %HA at all receptors are below the 6.5% target for the operation phase. The results indicate compliance with the Health Canada guidance. A sample calculation on the determination of change in %HA for receptor 76 near Gordon site during the operation phase is presented in Appendix C.

Table 6-9 Operation Phase - Change in %HA – Gordon Site

6.1.4.3 Health Canada Low Frequency Noise

As a target for the LFN issue, Health Canada noise guidance recommends that the energy sum of the linear sound levels in the 16, 31.5 and 63-Hz octave bands at a receptor location not exceeding 70 dBL.

Table 6-11 summarizes the predicted octave band sound level at 16 Hz, 31.5 Hz, and 63 Hz for the receptors near Gordon site during the construction and operation phases. Assessment of the 16 Hz sound pressure level is not possible because no sound power data is available for the proposed equipment and this octave band is outside of the ISO 9613-2 calculation standard, however Stantec's professional experience suggests that the 16 Hz octave band sound pressure level will be similar to that of the 31.5 Hz octave band. The sound levels at 16 Hz octave band were assumed to be the same as the sound levels at 31.5 Hz octave band. Potential of LFN noise effect is low at receptors near the Gordon site because the predicted sound level results are below the Health Canada target of 70 dBL.

Table 6-11 Sound Level at 16 Hz, 31 Hz, and 63 Hz Octave Band Frequency – Gordon Site

Receptor ID	Description	Construction Phase Predicted Daytime or Nighttime Sound Level, L_d or L_n (dB)				Operation Phase Predicted Daytime or Nighttime Sound Level, L_d or L_n (dB)

Note:
"-" Predicted noise level is negligible

Table 6-12 summarizes the predicted octave band sound level at 16 Hz, 31.5 Hz, and 63 Hz for the receptors near MacLellan site during the construction and operation phases. Similar to the results presented for Gordon site, potential for LFN noise effect is low at receptors near the MacLellan site because the predicted sound level results are below the Health Canada target of 70 dB.

Note:
"-" Predicted noise level is negligible

6.1.4.4 World Health Organization Sleep Disturbance

The outdoor nighttime annual sound level of 40 dBA was used as the sleep disturbance noise target for this assessment, based on the World Health Organization Night Guidelines for Europe (WHO 2009). The L_n results in Sections 6.1.1 and 6.1.2 (see Table 6-1 to Table 6-6) indicate that the nighttime equivalent sound level from the Project is below 40 dBA at residential receptors. No noise-related sleep disturbances of residential receptors are predicted from the Project operation during the nighttime period.

The work camp building design will affect the sound level experienced inside the work camp due to sound transmission loss through the building structure. Based on the work camp building design, a minimum of 30-dB noise reduction is expected for the building walls with the windows closed. Air conditioning units are recommended for the work camp building such that exterior windows and doors can be closed during summer season. The WHO (1999) recommends a target for sleep disturbance as being an indoor sound level of no more than 30 dBA. The predicted daytime or nighttime and level at the temporary work camp is 56.7 dBA during the construction phase. The predicted daytime or nighttime and level at the permanent work camp and 53.5 dBA during the operation phase. The construction phase noise level inside the temporary work camp is predicted to be 26.7 dBA. The operation phase noise level inside the temporary work camp is predicted to be 23 dBA. The indoor level predicted is based on a building transmission loss of 30 dB with the exterior windows and doors closed.

The predicted results during both construction and operation phases are therefore below the WHO 1999 indoor sound level target of 30 dBA. No noise-related sleep disturbances of workers are predicted from the Project operation during the daytime and nighttime period.

6.2 VIBRATION

6.2.1 Construction

The greatest distances that will result in a structural damage vibration level target of 5 mm/s (FTA 2018) and annoyance target of 72 VdB (FTA 2018) are summarized in Table 6-13.

Table 6-13 Greatest Distance for Structural Damage and Annoyance Vibration

Construction Equipment	Structural Damage Target Distance (m)	Annoyance Target Distance (m)
High Impact Piling	29	280
Excavator	8	71
Compactor	8	71
Bulldozer	4.5	42
Drilling	4.5	42

The distances presented in Table 6-13 are expected to be less for other heavy equipment required for construction that have lower vibratory emissions. The closest receptors to potential construction activities at the Gordon site or the MacLellan site are both located at a distance of more than 1 km. These receptors are located at sufficient distances that annoyance due to construction equipment vibration is expected to be unlikely. Table 6-14 summarizes the predicted vibration level for annoyance effect at the closest receptor for the Gordon site and the MacLellan site. The predicted vibration levels at both receptors are below the annoyance target of 72 VdB.

Table 6-14 Construction Activities Vibration Levels for Receptors

Receptor ID	Description	High Impact Piling (VdB, rms)	Excavator (VdB, rms)	Compactor (VdB, rms)	Bulldozer (VdB, rms)	Drilling (VdB, rms)
76 [1]	Potential Indigenous Receptor	60	42	42	35	35
86 [2]	Potential Indigenous Receptor	51	33	33	26	26

Note:
[1] closest receptor to the Gordon site
[2] closest receptor to the MacLellan site

6.2.2 Operation

Table 6-15 and Table 6-16 presents the prediction ground-borne vibration and air overpressure for receptors at the Gordon site and the MacLellan site, respectively. To be conservative in the predictions, the distance to each receptor was taken from the final pit boundary, and blasts were assumed to be fired with 208 kg of explosives.

The highest blast charge of 208 kg will result in ground-borne vibration below the vibration target of 10 mm/s at all receptors for the Gordon site. The predicted air overpressures are below the vibration target of 120 dBL at all receptors, with the exception of receptor ID 73 and ID 76 near the Gordon site. The predicted air overpressure at receptor ID 73 and 76 is 121 dBL and 123 dBL, respectively. When the blast charge is reduced from 208 kg to 43 kg per hole per delay, the predicted overpressures at receptor ID 73 and ID 76 meet the 120 dBL target.

The highest blast charge of 208 kg will result in ground-borne vibration below the vibration target of 10 mm/s at all receptors for the MacLellan site. The predicted air overpressures are below the vibration target of 120 dBL at all receptors, with the exception of the Permanent Work Camp in the MacLellan Site. The predicted air overpressure at the Permanent Work Camp is 127 dBL. This level is also above the Health Canada target of 125 dBL for one blast per day. In order to meet the Health Canada target of 125 dBL, the blast charge reduction to 85 kg per hole per delay is required. The reduced blast charge of 85 kg can be implemented initially to achieve the overpressure level of 125 dBL at the Permanent Work Camp. Reduced blast charge of 85 kg can be increased if monitoring results indicate air overpressure level below 125 dBL at Permanent Work Camp.

Primary factor in the blasting plan that influence the air overpressure is the charge-weight per delay. Charge weight dictates the amount of energy release. Decreasing the charge-weight per delay will effectively reduce the overpressure effect. The blasting plan will consider distance to receptors and will size the charges to avoid exceeding regulatory targets at receptors.

Other mine plan factors such as depth of burial, volume of displaced rock, delay time interval, and type of explosive will also affect the overpressure. A deeply buried or heavily confined charge will cause mostly ground vibration. Lightly confined blast will transfer most blast energy to atmosphere. Blast that displace large volume of rock create high air overpressure with low frequency content.

Air overpressure monitoring can be conducted at nearby receptors during a blast event to confirm vibrations are below regulatory targets. With mitigation measures, the overpressures are predicted to meet the most conservative target of 120 dBL at all receptors outside the PDA and 125 dBL at the Permanent Work Camp.

Table 6-15 Blast Related Vibration Levels for Receptors near Gordon Site

Receptor ID	Description	Distance to Open Pit (m)	Ground-borne Vibration (mm/s)	Air Overpressure with blast charge of 208 kg per hole per delay (dBL)	Air Overpressure with blast charge of 43 kg per hole per delay (dBL)
59	Potential Indigenous Receptor	8590	0.2	112	109
61	Potential Indigenous Receptor	10960	0.1	111	107
62	Potential Indigenous Receptor	14430	0.1	109	106
72	Potential Indigenous Receptor	3130	0.9	118	115
73	Potential Indigenous Receptor	2170	1.6	121 [a]	118
74	Potential Indigenous Receptor	3180	0.9	118	115
76	Potential Indigenous Receptor	1430	3.1	123 [a]	120
77	Potential Indigenous Receptor	2270	1.5	120	117
93	Black Sturgeon Residence Reserve	11850	0.1	110	107
101	Black Sturgeon Residence Reserve	11760	0.1	110	107
104	Remote Cottage	17070	0.1	108	105
126	Recreation Lot	13470	0.1	109	106
130	Remote Cottage	13290	0.1	110	106
131	Remote Cottage	4260	0.6	117	113
132	Trapper Cabin	3550	0.8	118	114
139	Park Vacation Home	13270	0.1	110	106

Note:

[a] exceeds the MECP cautionary target of 120 dBL based on the blast charge of 280 kg per hole per delay. However, the reduced charge as recommended in the mitigation section will lower the air overpressure to 120 dBL at Receptor ID 76.

Table 6-16 Blast Related Vibration Levels for Receptors near MacLellan Site

Receptor ID	Description	Distance to Open Pit (m)	Ground-borne Vibration (mm/s)	Air Overpressure with blast charge of 208 kg per hole per delay (dBL)	Air Overpressure with blast charge of 85 kg per hole per delay (dBL)
66	Potential Indigenous Receptor	9170	0.2	112	110
67	Potential Indigenous Receptor	7850	0.2	113	111

172	West Lynn Lake High School	7160	0.3	113	112
173	Lynn Lake Hospital	6200	0.3	114	112

Table 6-16 Blast Related Vibration Levels for Receptors near MacLellan Site

Receptor ID	Description	Distance to Open Pit (m)	Ground-borne Vibration (mm/s)	Air Overpressure with blast charge of 208 kg per hole per delay (dBL)	Air Overpressure with blast charge of 85 kg per hole per delay (dBL)
177	Lynn Lake Residence	6040	0.3	114	113
178	Lynn Lake Residence	6910	0.3	114	112
225	Lynn Lake Residence	7390	0.3	113	111
	Permanent Work Camp (outdoor)	800	7.4	127 [a]	125

Note:

[a] exceeds the Health Canada target of 125 dBL based on the blast charge of 280 kg per hole per delay. However, the reduced charge of 85 kg per hole per delay will lower the air overpressure to 125 dBA at the Permanent Work Camp.

6.2.3 Mitigation

The modelling results presented in Section 6.2.2 includes mitigation. In an adaptive management approach, mitigation measures presented in this section will be implemented as needed, and monitoring will help to confirm effectiveness.

Mitigation will be achieved by blast design. The mitigation measures that apply to both the Gordon and MacLellan sites are summarized as follows:

- Highest explosive per time delay that do not exceed 207.9 kg
- Only one hole/delay will be fired in the blast
- Minimum time delay between holes in blasts will not be less than 8 milliseconds (ms)

The specific mitigation measures for receptor ID 76 and ID 73 near the Gordon site are as follows:

- The reduced blast charge of 43 kg can be increased if the distance between the blast and closest receptor ID 76 and ID 73 is more than 1,430 m and 2,170 m (distance based on receptor location to pit boundary), respectively.
- The reduced blast charge of 43 kg can be increased if monitoring results indicate air overpressure level below 120 dBL at ID 76 and ID 73.
- Engagement with Marcel Colomb First Nation to discuss the potential of a seasonal mitigation approach, which relaxes the reduced blast charge of 43 kg during off-season period when trapping activities at receptors (ID 76 and ID 73) is not expected.

The specific mitigation measures for the Permanent Work Camp within the MacLellan site are as follows:

- Reduced blast charge of 85 kg can be increased if the distance between the blast Permanent Work Camp is more than 800 m.
- The reduced blast charge of 85 kg can be increased if monitoring results indicate air overpressure level below 125 dBL at the Permanent Work Camp.
- Blasting will be scheduled during shift change (e.g., less worker sleeping and more local activities) to reduce potential annoyance at the Permanent Work Camp.

7.0 SUMMARY AND CONCLUSION

A total of 32 noise and vibration receptors were identified in the vicinity of the Project sites, including residences, potential indigenous receptor areas, First Nation communities, schools, daycares, and hospitals.

The noise model focused on the potential Project noise effects during operation and construction phases. Blast related noise was considered as air blast overpressure effects in the vibration assessment. Noise effects such as community annoyance, sleep disturbance, and low frequency noise were assessed. The potential effects of Project activities on Noise were predicted to comply with the provincial, federal, and international noise targets (i.e. Province of Manitoba, Health Canada, and WHO) at all receptors.

The vibration model focused on the Project vibration effect during operation and construction phases. The construction phase vibration model focused on ground vibration from construction equipment. The potential effects of Project activities on vibration were predicted to meet the international vibration target (FTA 2018) during construction phase. The operation phase vibration model focused on the blast induced ground vibration and air blast overpressure effects. Blast designs were developed to avoid structural damage and reduce annoyance effects from blast induced ground vibrations and air blast overpressure. The results meet the provincial and federal vibration target during operation phase.

10.0 LIMITATIONS

This Technical Modelling report entitled Lynn Lake Gold Project, Noise and Vibration Impact Assessment was prepared by Stantec Consulting Ltd. ("Stantec") for the account of Alamos Gold Inc. (the "Client") to support the approvals and permitting process for the Lynn Lake Gold Project in Lynn Lake, Manitoba. In connection thereto, this document may be reviewed and used by the federal and provincial government agencies participating in the approvals and permitting process in the normal course of their duties; and stakeholders may provide comment as part of the regulatory approvals process. Except as set forth in the previous sentence, any reliance on this document by any third party for any other purpose is strictly prohibited. The material in it reflects Stantec's professional judgment in light of the scope, schedule and other limitations stated in the document and in the contract between Stantec and the Client. The opinions in contents of the document are based on conditions and information existing at the time the document was published and do not take into account any subsequent changes. In preparing the document, Stantec did not verify information supplied to it by others. Any unauthorized use that a third party makes of this document is the responsibility of such third party. Such third party agrees that Stantec shall not be responsible for costs or damages of any kind, if any, suffered by it or any other third party as a result of decisions made or actions taken based on unauthorized use of this document.

Title
Operation Phase Noise Contours - MacLellan Site

Appendix A COMMONLY USED NOISE AND VIBRATION TERMINOLOGY

Ambient Sound Level	The pre-project background noise or vibration level, which is often used interchangeably with “existing noise” in this manual.
Background Sound Level (i.e., Baseline)	It includes noise from all sources other than the sound of interest (i.e., sound from other industrial noise not being measured, transportation sources, animals, and nature)
Bands (octave, 1/3 octave)	A series of electronic filters separate sound into discrete frequency bands, making it possible to know how sound energy is distributed as a function of frequency. Each octave band has a centre frequency that is double the centre frequency of the octave band preceding it
Daytime	The hours from 7:00 am to 10:00 pm
day-night Sound Level (L_{dn})	An equivalent continuous sound level taken over 24 hours, with the night-time (10 p.m. to 7 a.m.) contributions adjusted by +10 dB. (This is a type of rating level because of the night-time adjustments.) The night-time adjustment (or addition of 10 dB to the night-time period) is used to account for the expected increased annoyance due to noise-induced sleep disturbance and the increased residential population at night relative to daytime, by a factor of 2–3. US EPA 1974 suggests that in quiet areas, the night-time levels naturally drop by about 10 dB and this level of adjustment has been used with success in the U.S.
dB/dBL/dBZ - Decibel	A logarithmic unit associated with sound pressure levels and sound power levels
dBA - Decibel, A-Weighted	A logarithmic unit where the recorded sound has been filtered using the A frequency weighting scale. A-weighting somewhat mimics the response of the human ear to sounds at different frequencies. A-weighted sound pressure levels are denoted by the suffix ‘A’ (i.e., dBA), and the term pressure is normally omitted from the description (i.e., sound level or noise level)
Decibel Addition	In acoustics, due to the logarithmic nature of the decibel scale, the addition of two or more sound pressure levels (denoted as SPL_1, SPL_2, … SPL_n) is done as follows: $SPL_1 + SPL_2 + \ldots SPL_n = 10 \log (10^{(SPL1/10)} + 10^{(SPL2/10)} + \ldots + 10^{(SPLn/10)})$ As an example: 50 dB + 50 dB = 53 dB

Energy Equivalent Sound Level (L_{eq})	An energy-average sound level taken over a specified period of time. It represents the average sound pressure encountered for the period. The time period is often added as a suffix to the label (e.g., L_{eq} (24) for the 24-hour equivalent sound level). L_{eq} is usually A-weighted. A L_{eq} value expressed in dBA is a good, single value descriptor of the annoyance of noise. Here is a list of L_{eq} used in this assessment: • $L_{eq,1hr}$ Hourly equivalent sound level • L_d Daytime period equivalent sound level (15 hours, 7:00 AM to 10:00 PM) • L_n Nighttime period equivalent sound level (9 hours, 10:00 PM to 7:00 AM) • L_{dn} day-night sound level (also see definitions for day-night Sound Level)
Frequency	Number of cycles per unit of time. In acoustics, frequency is expressed in hertz (Hz), i.e. cycles per second
Hertz (Hz)	Unit of measurement of frequency, numerically equal to cycles per second
Low Frequency Noise (LFN)	Noise in the low frequency range, 20 Hz up to 200 Hz. Health Canada guidance indicates that sounds in the 16, 31.5 and 63-Hz octave bands greater than 70 dB may result in noise-inducted rattles; Low frequency noise can be associated with the introduction of noticeable vibrations and rattles in some structures
Nighttime	The hours from 10:00 PM to 7:00 AM
Noise	Unwanted sound
Noise Level	Same as Sound Level, except applied to unwanted sounds
Sound	A dynamic (fluctuating) pressure
Sound Pressure Level (SPL)	The logarithmic ratio of the root mean square sound pressure to the sound pressure at the threshold of hearing. The sound pressure level is defined by equation below where P is the RMS pressure due to a sound and P_0 is the reference pressure. P_0 is usually taken as 2.0×10^{-5} Pascals. SPL (dB) = $20 \log(P_{RMS}/P_0)$
Sound Power Level (PWL)	The logarithmic ratio of the instantaneous sound power of a noise source to that of the reference power. The sound power level is defined by equation below where W is the sound power of the source in watts, and Wo is the reference power of 10^{-12} watts PWL (dB) = $10 \log(W/W_0)$
Spectrum	The description of a sound wave's resolution into its components of frequency and amplitude
Transmission Loss	The ratio of the sound energy striking an outside wall relative to the transmitted sound energy inside the wall, expressed in decibels.

Tonal Components	Often industrial facilities exhibit tonal components. Examples of tonal components are transformer hum, sirens, and piping noise. The test for the presence of tonal components consists of two parts (as per tonality prescribed in AUC Rule 012). The first part must demonstrate that the sound pressure level of any one of the slow-response, A-weighted, 1/3-octave bands between 20 and 16 kHz is 10 dBA or more than the sound pressure level of at least one of the adjacent bands within two 1/3-octave bandwidths. In addition, there must be a minimum of a 5 dBA drop from the band containing the tone within 2 bandwidths on the opposite side. The second part is that the tonal component must be a pronounced peak clearly obvious within the spectrum
VdB – Decibel, Vibration Velocity	Vibration Velocity Level (VdB) Ten times the common logarithm of the ratio of the square of the amplitude of the root mean square vibration velocity to the square of the amplitude of the reference RMS vibration velocity. The reference velocity in the United States is one micro-inch per second. Abbreviated as VdB.
Vibration	An oscillation wherein the quantity is a parameter that defines the motion of a mechanical system.

Appendix B NOISE EMISSION SOURCES

Appendix C EXAMPLE CALCULATION - % HIGHLY ANNOYED

This section presents a detailed sample calculation for the change in %HA at receptor 76 during the operation phase for the Gordon site. The %HA is calculated by the adjusted day-night sound level ($L_{dn,adjusted}$) using equation F4 in Appendix F of Health Canada 2017:

$$\%HA = 100 / [1 + e^{(10.4 - 0.132 * Ldn,adjusted)}] \qquad [F4]$$

Adjusted Baseline Day-night Sound Level

At receptor 76, the "peace and quiet" adjustment of +10 dB is added to the baseline L_{dn} of 40 dBA (Table 4-3), resulted in the adjusted baseline $L_{dn,\ adjusted}$ of 50 dBA.

Baseline %HA

The baseline %HA of 2.17 % is based on the adjusted baseline $L_{dn,\ adjusted}$ of 50 dBA in equation F4 as follows:

$$\text{Baseline } \%HA = 100 / [1 + e^{(10.4 - 0.132 * 50\ dBA)}] = 2.17\ \%$$

Adjusted Cumulative Day-night Sound Level

The cumulative day-night sound level is determined by adding the baseline sound level 40 dBA (Table 4-3) to the project sound level of 44.9 dBA (Table 6-4) at receptor 76. The cumulative day-night sound level of 46.1 dBA is calculated as follows:

$$\text{Cumulative } L_{dn} = 10 \log[10^{(0.1 \times 40\ dBA)} + 10^{(0.1 \times 44.9\ dBA)}] = 46.1\ dBA$$

The adjusted cumulative day-night sound level $L_{dn,\ adjusted}$ of 56.1 dBA is determined by adding the "peace and quiet" adjustment of 10 dB to the cumulative L_{dn} of 46.1 dBA.

Cumulative (Baseline and Project) %HA

The cumulative (Baseline and Project) %HA of 4.77 % is based on the adjusted cumulative day-night sound level of 56.1 dBA in equation F4 as follows:

$$\text{Cumulative } \%HA = 100 / [1 + e^{(10.4 - 0.132 * 56.1\ dBA)}] = 4.77\ \%$$

Change in %HA

The change in %HA of 2.60 % is determined by the different in the cumulative (Baseline and Project) %HA of 4.77 % and Baseline %HA of 2.17 %.

Lynn Lake Gold Project Hydrology Water Balance and Water Quality Impact Assessment: Gordon Site

1.0 INTRODUCTION

The Lynn Lake Gold Project (LLGP; or “the Project”) consists of two primary deposit sites, which are both located near Lynn Lake, Manitoba: the ‘Gordon’ site and the ‘MacLellan’ site. Alamos Gold Inc. (Alamos) intends to construct (redevelop), operate and eventually close/reclaim open pit gold mines at both these historical mine sites. The Gordon site is located approximately 55 kilometres (km) east of Lynn Lake, Manitoba (by vehicle), and the MacLellan site is located approximately 8 km northeast of Lynn Lake (by vehicle) (Map 1, Appendix A). Lynn Lake is located approximately 820 km northwest of Winnipeg.

This Hydrology Water Balance and Water Quality Technical Modeling Report (TMR) for the Gordon site has been prepared to assess the potential effects of the construction, operation, and closure phases of the Project on surface water resources (water quantity and water quality) at the Gordon site. The TMR considers the Gordon site components of the Project, baseline data collected for the Project since 2015, and comments received from agencies, Indigenous communities, and other stakeholders.

To evaluate the effects of the Project, a water balance and water quality model (WBWQM) has been developed for the Gordon site to:

- Estimate the quantity and quality of surface water runoff associated with the Project including the open pit, mine rock storage area (MRSA) and the ore stockpiles during all phases.
- Predict the quantity and quality of water that will be discharged to the environment during all phases.
- Estimate quantity and quality of surface water in the environmental receptors for baseline condition and during all phases.
- Aid in the development of the conceptual closure plan for the Project.

This TMR, and a companion TMR conducted for the MacLellan site (Stantec 2020a), form part of the supporting documentation for the Environmental Impact Statement/Environmental Assessment completed for the Project.

1.1 PROJECT BOUNDARIES

1.1.1 Gordon Project Development Area (PDA)

The Gordon Project Development Area (PDA) encompasses the immediate area in which Project activities and components may occur plus a 30-metre (m) buffer (Map 1-2, Appendix A). It is the anticipated area of direct physical disturbance associated with the construction and operation of the Project. At the Gordon site, the PDA includes two legacy open pits (Wendy and East pits), and the legacy diversion channel between Gordon and Farley lakes. Except for the existing access road, the Gordon site is located entirely within the Farley Lake watershed. All former buildings and infrastructure associated with legacy mining activities have been removed. The size of the Gordon PDA is approximately 5 square kilometres (km^2).

1.1.2 Gordon Local Assessment Area (LAA)

The Gordon Local Assessment Area (LAA) includes the PDA, the former Farley Lake mine site and watercourses and lakes potentially affected by the Project (see Map 1-2, Appendix A). The Gordon site, formerly called the Farley Lake site, was operated between 1996 and 1999 as an open pit gold mine. After closure, the site underwent a reclamation process. In addition to the components described above in the PDA, the existing infrastructure at the site includes a 15-kilometre (km) gravel access road, a bridge across the Hughes River, two reclaimed mine rock storage areas and two overburden storage areas that have been capped. The LAA includes lakes and streams with the Ellystan Lake watershed, a sub-watershed in the Hughes River system. The LAA extends to the outlet of Ellystan Lake and is approximately 47.5 km^2. The LAA also represents the extent of the WBWQM.

1.1.3 Regional Assessment Area (RAA)

The Gordon LAA is one small component of the Regional Assessment Area (RAA). The RAA represents an area of approximately 9,929 km^2. The RAA includes the drainage area that encompasses the PDAs and LAAs of both Project sites (Gordon and MacLellan) and the streams and lakes that drain the LAAs to a common downstream location (i.e., Granville Lake). It also includes upstream lakes and streams in the Keewatin River watershed to provide regional context for the lakes and streams within the LAAs and has been defined to allow assessment of potential cumulative effects resulting from the interaction of the Project with past, present, and reasonably foreseeable future projects. The RAA is not included in the Gordon model domain, beyond the Gordon LAA.

1.2 PROJECT PHASES AND COMPONENTS

Alamos proposes to develop a conventional open pit with shovel and truck removal of the mine rock and ore produced during blasting at the Gordon site. Infrastructure at the Gordon site will be limited to the open pit, ore and overburden stockpiles, a MRSA, and minor supporting infrastructure for equipment storage and maintenance. Ore from the Gordon site will be shipped to the MacLellan site for processing.

1.2.1 Mine Life Phases and Mine Plan

For modelling purposes, the third Project phase, decommissioning/closure, was sub-divided into two sub-phases of active closure and post-closure. On this basis, the phases of the Project considered in the WBWQM included construction, operation, active closure, and post-closure. Each phase is described in Table 1-1, including the time lengths for each.

Table 1-1 Project Phases and Model Time Frames

Project Phase	Time Frames Incorporated into the Model	Description
Baseline	Prior to Year -2	Mine activity does not occur during this phase. The baseline time frame is extended in the model to allow reservoirs within the model to reach steady state conditions.
Construction	Year -2 – Year -1 (2 years)	During this phase, the two legacy open pits will be dewatered, and the interceptor wells start operating. A temporary ore stockpile will be developed.
Operations	Year 1 – Year 6 (6 years)	During this phase, the open pit will be developed, a MRSA will be constructed, and ore will be shipped to the MacLellan site.
Active Closure	Year 6 – Year 11 (6 years)	During this phase, the MRSA will be recontoured and reclaimed and the open pit will be allowed to fill with water.
Post-Closure	Year 12 – Year 128 (117 years)	During this phase, the open pit fills and eventually discharges to the environment. Other discharges to the environment include groundwater and surface water runoff from the MRSA.

1.2.2 Project Components

In this section, individual Project components (legacy and proposed) and catchment areas at the Gordon site are discussed and shown on Map 1-3 (Appendix A).

1.2.2.1 Legacy Mine Components

East and Wendy Pits - Water from both East and Wendy pits will be pumped and discharged into Farley Lake during construction.

Legacy Mine Rock Storage Areas - The legacy MRSA located north of the legacy pits (North MRSA) will not be disturbed as a result of Project activities. The legacy MRSA located south of the legacy pits (South MRSA) will be partially disturbed (with the disturbed portion relocated to the proposed MRSA; see Section 1.2.2.2).

1.2.2.2 Proposed Mine Components

Interceptor (Dewatering) Wells - A series of interceptor (dewatering) wells will be installed between the ultimate footprint of the proposed open pit and Gordon and Farley lakes. The wells will be used to reduce groundwater inflow into the open pit, thus limiting contact water, during mine construction and operation as well as maintaining the water elevations in both lakes.

Open Pit - A new open pit will be developed that will encapsulate the legacy East and Wendy pits. The pit will be developed in a series of benches with drilling and blasting completed on each bench. Blasting will be achieved using emulsion explosives with non-electric detonators. The proposed depth of the Gordon open pit is approximately 190 m and will have an ultimate surface area at the ground level of 335,945 m^2.

The total quantity of material to be mined from the Gordon open pit during Project mine operation is approximately 58.98 million tonnes (Mt), which includes ore material of 8.00 Mt (Q'Pit 2019).

Ore Stockpiles - The estimated maximum volume of ore is 0.7 million cubic metres (Mm^3). A temporary ore stockpile will be required for ore contained within material excavated from the first benches of pit construction. A short-term high-grade stockpile will be constructed to provide access both from the open pit and the external mine trucks. The material will be transported via highway trucks to the mill feed storage area and crushing plant at the MacLellan site for short-term storage and initial crushing before it is used as feedstock for the adjacent ore milling and processing plant. Mine operations at the Gordon site are currently planned to cease after Year 5. The transfer of stockpiled ore, however, will continue into Year 6 of the current mine plan. Longer term lower-grade run-of-mine (ROM) stockpiles will be also be constructed. The ore in these piles will eventually be transferred to MacLellan for processing but will remain in place for longer than the higher-grade ore in the short-term pile.

Overburden Stockpile – The estimated volume of material in the overburden stockpile is 0.5 Mm^3. The overburden material will be stripped during construction and used for reclamation activities during closure.

Mine Rock Storage Area - The estimated maximum volume in the MRSA is 22.3 Mm^3 of mine rock. The MRSA will be developed during operations. During closure the MRSA will be recontoured and reclaimed.

Collection Ditches - During construction, seepage/runoff collection ditches will be constructed around the perimeter of each stockpile/storage area and directed to a series of sumps and/or small ponds located at topographic lows. Water collected in the sumps and/or small ponds will be pumped to a site water collection pond for management and/or treatment (if required) prior to discharge. The collection ditches are assumed to be decommissioned during closure.

Sewage Treatment – Sewage from the Gordon site buildings will be collected locally in two septic tanks and will be trucked to MacLellan for processing.

2.0 MODELLING APPROACH

The WBWQM was constructed using GoldSim simulation software with the contaminant transport (CT) module add-on extension. GoldSim software is commonly used in the mining industry to develop water balances and to predict water quality at user-defined modelling nodes by combining system dynamics with discrete event simulations. The model was run dynamically on a daily time step for the construction, operation, active closure and post-closure phases. Results are presented and interpreted based on monthly averaged values.

The model is compartmentalized into the Water Balance (WB) and the Water Quality Model (WQM). The WB is calculated by incorporating defined inputs, such as inflow rates and outflow rates into the WQM. These inflows and outflows are based on precipitation rates, catchments and facility areas and volumes, groundwater inflow and outflow rates, operational water management strategies and the movement of materials within and out of the site. The water quality predictions are calculated at the model nodes by integrating source term development (loading sources) into the WB.

The WB consists of two sub-models to facilitate the evaluation of the “relative” impacts of the Project on the baseline environment. The first sub-model is the baseline water balance (BL-WB) and the second sub-model is the project water balance (PROJ-WB). The PROJ-WB was developed to predict changes in flows to the receiving environment and within the Project site during each phase of mine life. The BL-WB was developed to predict baseline flows across the site throughout the life of the mine assuming the Project does not occur, and it runs concurrently within the GoldSim platform with the PROJ-WB, to facilitate comparison between non-Project and Project conditions at each time step in the model.

Like the WB, the WQM consists two sub-models, the baseline water quality model (BL-WQM) and the Project water quality model (PROJ-WQM) to facilitate comparison between non-Project and Project conditions.

Within the WBWQM, model nodes are representative of water monitoring stations. Creeks, streams or rivers are represented by a flow-through function in the WB, for which inflow equals outflow. Lakes are represented by reservoirs in the WB for which inflow equals outflow plus or minus storage. The model nodes are often represented as cells in the WQM; the flow through and within the cell is dependent on the WB, while loads can be added independently to the WBWQM. A load refers the amount of mass entering a model reservoir. The WB and WQM are presented in Section 3.0 and Section 4.0, respectively.

Three climate scenarios were considered to evaluate the potential effects of the Project on surface water. The WB and climate scenarios are discussed in more detail in Section 3.0. Two load scenarios are included in this TMR to evaluate the sensitivity of the source terms on the predictions and to aid in the development of a contingency planning (Section 4.0).

3.0 WATER BALANCE

3.1 GENERAL APPROACH

The following subsections present the approaches used for modelling water quantity with the WB. The WB provides estimates of streamflow and water levels from the existing watersheds, rivers and lakes.

As introduced above, the WB consists of two models:

Baseline Water Balance (BL-WB): Models the baseline condition or pre-Project phase, with no proposed mine features. The model boundary is the LAA. The baseline model was calibrated using data from 2015-2016.

Project Water Balance (PROJ-WB): This model is built within the BL-WB and includes the proposed Project infrastructure and water management of the mine within the PDA as well as all other non-Project affected watersheds within the LAA.

The model includes various climate scenarios intended to define the potential range of flows and water levels considering uncertainty associated with inputs and assumptions. The general approach was to:

- Develop the BL-WB that includes lakes (reservoirs) for the sub-watersheds within the LAA.
- Calibrate the BL-WB to a period of measured climatic and hydrologic data from 2015 and 2016.
- Use the calibrated BL-WB to estimate the baseline streamflow and water levels for all climate scenarios.
- Develop the PROJ-WB by adding Project-specific components and flows to the BL-WB.
- Estimate streamflows and water levels during all phases of the Project.
- Compare the BL-WB stream flows and lake water levels to the PROJ-WB predictions during all phases of the Project for wet, dry, and average conditions.

3.2 BASELINE WATER BALANCE STRUCTURE

This section describes the inputs used to calibrate the BL-WB. The BL-WB was developed to model the baseline conditions of the LAA. This includes watersheds within the PDA, as well as all watersheds and sub-watersheds connected to the Ellystan Lake watershed (i.e., those contained within the LAA). The BL-WB models the LAA without the Project and represents the baseline or pre-Project conditions.

3.2.1 Baseline Water Balance Conceptual Model

The BL-WB is developed to predict streamflow for sub-watersheds and lake levels within the LAA of the Gordon site. The watersheds modelled are shown in Map 3-1 (Appendix A), with more detail on the Gordon site watersheds provided in Map 3-2 (Appendix A). Details of the BL-WB input parameters and the calibration of the model are provided below in Section 3.2.3 and Section 3.2.4.

For the BL-WB, the Snowmelt-Runoff Model (SRM) was selected to represent the physical processes observed at the site. The model was run on a daily time step and calculated the runoff from each watershed and integrated into lake water balance model for lakes in the modelled area. For each lake a stage-volume and stage-area relationship was used to balance the water in the lake and determine lake levels for model calibration and lake volumes for water quality modelling. The model provides an integrated hydrology and water balance. Table 3-1 presents a list of the watersheds modelled for the Gordon site. Figure 3-1 (Appendix B) presents a conceptual model for how the watershed and the lakes are connected in the WB.

The BL-WB was calibrated iteratively to measured streamflow and lake water level data during 2015 and 2016 at a number of hydrometric stations shown on Map 3-2 (Stantec 2017a). Statistical assessment of the BL-WB was performed to measure the model’s performance. Detailed model inputs, calibration parameters and statistical assessment of the calibration is provided Section 3.2.3 and Section 3.2.4.

Table 3-1 Watersheds Modelled in the Gordon LAA

Watershed Name	Sub-Watershed Name	Model Name	Waterbodies and Project Components within Watershed or Sub-Watershed	Area (km²)
ws-FAR5 (Gordon site watershed)	sws-FAR7-A1	FO1	MRSA and Overburden Stockpile	1.5
	sws-FAR7-B1	F10	n/a*	0.5
	sws-FAR7-C1	F03sub	n/a*	1.4

	sws-FAR5-MAR1	F04	Unnamed lake FAR5-MAR2	0.9
	sws-FAR5-MAN2	F05ex1	Marnie Lake	1.0
	sws-FAR5-MAN1	F05ex2	n/a*	0.5
	sws-FAR5.2	F05	Upper Farley Lake and Diversion Channel	2.2
	sws-FAR5.1	F05	Lower Farley Lake	0.6
ws-FAR3-SIM1	n/a	FLSA2	White Owl Lake and Mac Lake	8.0
ws-FAR3	n/a	FLSA3	Swede Lake	13.0
ws-FAR2-WHI1	n/a	FLSA2	White Owl Lake and Mac Lake	11.0
ws-FAR1	n/a	FLSA1	Ellystan Lake	16.0
ws-SUS4	n/a	FLSA4	Pump Lake and Simpson Lake	1.2

3.2.2 Baseline Water Balance Description

The SRM is designed to simulate streamflow at a daily timestep (additional details are provided in Martinec et al., 2008). Streamflow generated from snowmelt and rainfall is computed, using the following equation (*Equation 3-1*):

$$Q_{n+1} = [C_{Sn}.a_n(T_n + \Delta T_n)S_n + C_{Rn}P_n]\frac{A.10000}{86400}(1 - K_{n+1}) + Q_nK_{n+1} \qquad \textit{Equation 3-1}$$

Where:

Q = average daily discharge ($m^3 s^{-1}$)

C = runoff coefficient; expresses losses to streamflow as a ratio (runoff/precipitation), with C_S referring to snowmelt and C_R to rain

a = degree-day factor (cm °C^{-1} d^{-1}) indicating the snowmelt depth resulting from 1 degree-day

T = number of degree-days (°C d)

ΔT = the adjustment by temperature lapse rate when extrapolating the temperature from the station to the average hypsometric elevation of the basin or zone (°C d)

S = ratio of the snow-covered area to the total area

P = precipitation contributing to runoff (cm).

T_{CRIT} = threshold temperature that determines whether the precipitation is rainfall or snow. A threshold temperature is used to decide whether a precipitation event will be treated as rain ($T \geq T_{CRIT}$) or as new snow ($T < T_{CRIT}$). If precipitation is determined by T_{CRIT} to be new snow, it is kept on storage over the hitherto snow free area until melting conditions occur.

A = area of the sub-catchment [km^2]

K = recession coefficient indicating the decline of discharge in a period without snowmelt or rainfall:

n = sequence of days during the discharge computation period.

$\frac{10000}{86400}$ = conversion from cm·km^2 d^{-1} to m^3 s^{-1}

T, S and P are variables measured or determined each day, C_R, C_S, are lapse rates to be determined, ΔT, T_{CRIT}, K and the lag time are parameters which are characteristic for a given basin or, more generally, for a given climate. The lag time is the time difference between the start of increasing temperatures and the corresponding increase in runoff from the basin.

All parameters with unknown values (S, C_R, C_S, *K, a)* were determined during the calibration process.

3.2.2.1 Lake Level and Lake Outflow

Where no stage-discharge relation was available for lakes in the LAA, the relation was estimated using *Equation 3-2*:

$$Q_{out} = CD * (Lake\ Water\ Level - H_O)^{P} \qquad \textit{Equation 3-2}$$

Where:

Q_{out} = Lake Outflow (m^3/s)

CD = Lake Coefficient

H_o = Minimum water level for lake outflow (m^3/s)

P = Power Coefficient (m^3/s)

All parameters with unknown values (CD, Ho, P*)* were determined during the calibration process.

3.2.2.2 Baseline Water Balance Calibration

Models are mathematical approximations of physical systems. Calibration is a process wherein certain parameters of the model are altered in a systematic fashion and the model is run iteratively until the computed values matches the observed values within a range that is considered acceptable. The GoldSim model optimization tool was used for model calibration of the SRM. Model performance is measured in terms of the ability to reasonably predict key response variables such as streamflow and lake level. Statistical assessment of the calibrated hydrology model was performed to measure model performance. The following statistical parameters were used:

Nash-Sutcliffe Model Efficiency

The Nash–Sutcliffe model efficiency coefficient, was used to assess the predictive results (flow or lake level) of the BL-WB (*Equation 3-3*). The Nash–Sutcliffe model efficiency coefficient (*E*) is defined as (Nash and Sutcliffe, 1970):

$$\boldsymbol{E = 1 - \frac{\sum_{t=1}^{T}\left(Q_o^t - Q_m^t\right)^2}{\sum_{t=1}^{T}\left(Q_o^t - Q_{o,av}\right)^2}}$$

Equation 3-3

Where:

Q_o is observed value

Q_m is modelled value

$Q_{o,avg}$ is average observed value

Generally, Nash–Sutcliffe coefficient ranges from $-\infty$ to 1 with a value of 1 indicating a perfect match of modelled value to the observed data (i.e., the closer the model efficiency to 1, the more accurate the model is). An efficiency of 0 indicates that the model predictions are as accurate as the mean of the observed data. An efficiency less than zero indicates that the observed mean is a better predictor than the model.

Correlation Coefficient

The Pearson's Correlation Coefficient (R) indicates the strength and direction of a linear relationship between the model output and observed values. It is obtained by dividing the covariance of the two variables by the product of their standard deviations (*Equation 3-4*).

$$R = \frac{\sum_{t=1}^{T}(Q_o^t - Q_{o,avg}).(Q_m^t - Q_{m,avg})}{\sqrt{\sum_{t=1}^{T}(Q_o^t - Q_{o,avg})^2 . \sum_{t=1}^{T}(Q_m^t - Q_{m,avg})^2}} \qquad \text{Equation 3-4}$$

Where: $Q_{m,avg}$ is average modelled value for the simulation period, and other variables are as previously defined.

Further details on inputs and calibration are discussed in Section 3.2.3 and Section 3.2.4.

3.2.3 Baseline Water Balance Inputs

3.2.3.1 Climate

Historical climate data were gathered from the Environment and Climate Change Canada (ECCC) National Climate Data and Information Archive (ECCC 2019). Climate data relevant to the Project area is available from four ECCC meteorological stations (Stantec 2017b): Lynn Lake Airport (Climate ID 5061646), Lynn Lake (Climate ID 5061648), Lynn Lake (Climate ID 5061645), and Lynn Lake Reference Climate Station (RCS) (Climate ID 5061649). These four stations were chosen because of their proximity to the Project area and relatively long period of record. Stations 5061646, 5061648, and 5061645 are located at the Lynn Lake Airport and Station 5061649 is located just south of the airport. The Lynn Lake climate stations encompass data from 1968 to 2005 (5061646), 2005 to 2014 (5061648), and 2010 to 2017 (5061645 and 5061649). Together these stations have a continuous record going back more than 40 years; this record was used to generate historic temperature and precipitation. Stations 5061645 and 5061649 are currently in operation. Daily temperature, precipitation, and snowfall data were downloaded and used for input.

The summary of the average temperature, precipitation, and snow on ground data for the 2015 and 2016 water years and climate normals (1981-2010) at the Lynn Lake stations (the combined record of ECCC stations 5061645 and 5061649) is provided in Table 3-2.

The 2015 and 2016 daily climate data were used for model calibration periods. The historical climate data were used to develop the average, 25-year wet and 25-year dry climate scenarios for the model simulations (see Section 3.3.2). The Prairie Farm and Rehabilitation Administration (PFRA) estimated the Lynn Lake annual lake evaporation rate to be 476 mm based on historical gross evaporation data (PRFA 2002), with the maximum monthly evaporation rate occurring in July (Table 3-3). The monthly lake evaporation data were used in the WB for the lake and pond (open pit and collection ponds) models.

Table 3-2 Summary of Climate Normals (1981 – 2010) and Meteorological (2015 and 2016) Data at Lynn Lake, MB (ECCC 2019)

3.2.3.2 Watershed Areas

A geographic information system mapping approach was used to delineate sub-watersheds for the Gordon Site. Site-specific Light Detecting and Ranging (LiDAR) data at approximately 2 m x 2 m resolution was used. For areas where LiDAR coverage was not available, digital elevation model data from GeoBase (Natural Resources Canada 2014) at approximately 20 m x 20 m resolution was used. A naming system was designated for all reaches in the Gordon LAAs; where *ws* stands for watershed and *sws* stands for sub-watershed. Table 3-4 presents watershed characteristics.

Table 3-4 Physiographic Characteristics of Watersheds

Watershed Name	Sub-Watershed Name	Waterbodies and Project Components within Watershed or Sub-Watershed	Area (km²)	Minimum Elevation (m)	Maximum Elevation (m)	Lake Coverage (%)	Tributary to
ws-FAR5 (Gordon site watershed)	sws-FAR7-A1	MRSA and Overburden Stockpile	1.5	345	317	0	Gordon Lake
	sws-FAR7-B1	n/a*	0.5	351	315	0	Gordon Lake

3.2.3.3 Lake Bathymetry

Lake bathymetric data were collected at key lakes. Waterbodies were chosen based on their proximity to the proposed mine operations and potential to be physically altered by the proposed development. Within the Gordon LAA, waterbodies included Farley Lake, Gordon Lake, Wendy Pit, and East Pit. Additional details of the bathymetric field program are presented in Stantec 2017a. Lake volume-elevation and lake area-elevation relationships were established using the lake bathymetric data and topographic information surrounding the lake and used as an input to the lake water balance model. The results of lake surface area and volume for average lake levels in the hydrology model for the Gordon site are presented in Table 3-5.

Table 3-5 Lake Surface Areas and Volumes for the Gordon LAA

Lake Name	Surface Area (m^2)	Volume (m^3)
Wendy Pit	44,100	573,930
East Pit	58,460	1,561,931
Ellystan Lake	2,507,299	7,378,240 *
Gordon Lake	190,292	260,370
Simpson Lake	1,719,038	2,578,557 *
Farley Lake	773,944	724,960
Swede Lake	2,305,012	7,376,000
* No data available, estimated based on local experience		

3.2.3.4 Measured Streamflow and Water Level

The locations and watersheds of the hydrometric stations that are used for model calibration are shown in Table 3-6. Only one station (QF08) had sufficient data to produce a stage-discharge relationship and subsequent calculation of discharge for the 2015 and 2016 monitoring period (Stantec 2017a). The remaining stations were limited to stage data and point measurements of discharge, except for QF03 where no flow was observed throughout the monitoring period. A more thorough explanation of the data limitations and field data analysis are provided in Stantec 2017a. The measured discharge at monitoring stations QF08 and lake water level data at monitoring stations QF03, QF05, QF06, QF07 and QF08 were used for BL-WB calibration. The drainage areas in Table 3-6 differ from the catchment areas in Table 3-1 in that those listed in Table 3-6 represent the cumulative watershed area that drains to the hydrometric station.

Table 3-6 Geographic and Physiographic Details for the Gordon Hydrometric Monitoring Stations Used in the Model

Station	UTM Coordinates (Zone 14V)	Period of Operation	Available Parameters for model calibration	Area (km^2)	% Lakes	Description
QF03	411995 E 6308030 N	May 29, 2015 - present	Water Level	4.3	4.4	Gordon Lake. This station is intended to measure outflows from Gordon Lake into the diversion to Farley Lake.
QF05	414317 E 6307228 N	May 28, 2015 - present	Water Level	13.3	9.3	Outlet of Farley Lake, to the east. The objective of this station is to measure outflows from Farley Lake.
QF06	411577 E 6303510 N	May 30, 2015 - present	Water Level	8.0	21.9	Outlet of Simpson Lake into Swede Lake. Flows are measured downstream of the culvert connecting the two lakes.
QF07	414759 E 6303927 N	May 30, 2015 - present	Water Level	34.5	15.8	Outlet of Swede Lake.

Table 3-6 Geographic and Physiographic Details for the Gordon Hydrometric Monitoring Stations Used in the Model

Station	UTM Coordinates (Zone 14V)	Period of Operation	Available Parameters for model calibration	Area (km^2)	% Lakes	Description
QF08	413309 E 6298252 N	May 27, 2015 - present	Water Level, Discharge	61.8	18.8	Downstream of the outlet of Ellystan Lake

3.2.3.5 Groundwater

Groundwater discharge to the lake and lake discharge to the groundwater system were predicted for Gordon, Farley and Susan lakes for baseline conditions using a hydrogeological model (Stantec 2020b). The steady-state calibrated groundwater flow model was used to quantify baseline groundwater levels and flow and groundwater discharge to the receiving environment under baseline conditions.

The estimated groundwater discharges to the lakes under baseline conditions is presented in Table 3-7. The groundwater discharge to the lake and lake discharge to groundwater were used as inputs to the lake water balance model (Stantec 2020b).

Groundwater also discharges to rivers as baseflow. Baseflow estimates in the model are based on inflows calibrated in the BL-WB using the SRM model.

Table 3-7 Estimated Groundwater Discharges for Lakes under Baseline Conditions (Stantec 2020b)

Lakes	Groundwater to Lake (m^3/s)	Lake to Groundwater (m^3/s)	Net Groundwater Inflow (m^3/s)
Susan Lake	0.00041	0.00005	0.00036
Gordon Lake	0.00074	0.00016	0.00058
Farley Lake	0.00450	0.00209	0.00241

3.2.4 Baseline Water Balance Calibration

3.2.4.1 Model Calibration

The BL-WB was calibrated based on streamflow and lake water level measurements at monitoring stations described in Section 3.2.3 for the period June 2015 to June 2016.

The overall calibration strategy was to compare the model results to observed datasets for the period of record (Stantec 2017a). The calibration was done by generating and comparing simulated and observed monthly and daily average streamflow and simulated and observed daily average lake water levels. Precipitation from June 1, 2015 to September 31, 2016 were used as inputs into the model. The model results were compared to observed values and the parameters comprising the SRM were adjusted until a satisfactory calibration was obtained.

During model calibration, runoff coefficient (*C*), recession coefficient (*K*) and degree-day factor (*a*) were adjusted for each watershed; and lake coefficient (*CD*), minimum water level for lake outflow (*Ho*) and Power Coefficient (*P*) were adjusted for each lake. Runoff coefficient values are different during rain and snowmelt periods for a given watershed. Snowmelt period is the time where the temperature is below a threshold temperature that determines whether the precipitation is rainfall or snow. The rain period is the time where the temperature is above threshold temperature.

3.2.4.2 Calibration Result

Streamflow

As indicated above, streamflow data were only available for monitoring station QF08, this data was used to calibrate the BL-WB (see Stantec 2017a). Figure 3-2 and Figure 3-3 (Appendix B) show monthly and daily measured and simulated streamflow at monitoring station QF08. The model captures the seasonal patterns of the observed streamflow. Statistical assessment of the model performance is presented in Section 3.2.4.3.

Lake Level

Lake level data were available at monitoring stations QF03 (Gordon Lake), QF05 (Farley Lake), QF06 (Simpson Lake), QF07 (Swede Lake) and QF08 (Ellystan Lake) and used to calibrate the BL-WB (Stantec 2017a). Figure 3-4 to Figure 3-8 (Appendix B) show daily measured and simulated lake level at the five monitoring stations. The model captures the observed seasonal lake level patterns for Gordon Lake, Simpson Lake and Ellystan Lake however, the model sometimes under-predicts and sometimes over-predicts lake levels at Farley Lake and Swede Lake. Given the extensive beaver activity in the area (Stantec 2017a), the simulated daily lake level generally compared well with the measured lake level. Statistical assessment of the model performance is presented in Section 3.2.4.3.

3.2.4.3 Statistical Assessment

Table 3-8 shows the Nash–Sutcliffe coefficient (*E*) and correlation coefficient for the average monthly and daily discharge at QF08, and monthly lake levels at QF03, QF05, and QF07. The *E* for the monthly and daily average discharges at QF08 is greater than 0, which indicate the predictive power of the model at QF08 is as good as the observed values. The *E* for the monthly average lake level at QF03, QF05 and QF07 are greater than 0, which indicate the predictive power of the model is as good as the observed values. The simulated average monthly lake levels are also well-correlated with R values of 0.90 and 0.94 and 0.74 at QF03, QF05 and QF07, respectively.

Table 3-8 Hydrology Model Performance Parameters

Parameter	Monthly Discharge	Daily Discharge	Lake Level Monthly		
	QF08	QF08	QF03	QF05	QF07
Nash-Sutcliffe Coefficient (E)	0.59	0.39	0.81	0.86	0.54
Correlation Coefficient (R)	0.83	0.65	0.90	0.94	0.74

3.2.4.4 Application of Baseline Water Balance

With calibration of BL-WB complete, the PROJ-WB was constructed. The PROJ-WB will be used to assess potential effects of the Project on surface water flow and lake levels. This is accomplished through comparison of BL-WB streamflows to PROJ-WB streamflows (or BL-WB lake levels to PROJ-WB lake levels) during all phases of the Project (construction, operation, active closure, and post-closure phases).

3.3 PROJECT WATER BALANCE STRUCTURE

This section presents the conceptual model inputs and assumptions used to develop the PROJ-WB and includes a discussion of baseline catchments that change due to the Project as well as a discussion of the mine site and operational flows. The modelling assumptions used in watersheds that change as a result of the Project are described below.

3.3.1 Project Water Balance Conceptual Model

The PROJ-WB includes components of the BL-WB and details related to the overall Project mine plan from construction, operation, active closure, and post-closure.

The sub-watershed areas affected by site infrastructure were subtracted from the baseline watershed areas for each sub-watershed, and the streamflow from the unaffected watershed is estimated using the BL-WB. The PROJ-WB was used to estimate streamflow and lake level during all phases of the Project.

Figure 3-9 (Appendix B) presents the model structure of the PROJ-WB and highlights the model nodes, the Gordon PDA, and identifies which nodes are associated with either contact water (water that has contacted the Project) or non-contact water (water not affected by the Project).

For conservatism in the model, it is assumed that the catchment area for all mining features are fully realized at start of construction. This means that contact water from stockpiles start flowing to the collection ponds at the beginning of construction. Dewatering of Wendy and East pits also starts with construction, discharging into Farley Lake, this has been modelled to last for 20 months. During dewatering of the legacy pits, interceptor wells are also turned on in the model. The interceptor wells are designed to limit losses from Gordon and Farley lakes due to the increased losses to groundwater associated with the development of the open pit, as well as to limit the volume of contact water.

The following sections present a summary of the Project, schedule and the overall modelling approach used for the PROJ-WB. Wherever possible, conservative assumptions have been included in the modelling approach for the purposes of predicting potential environmental effects.

The Project components at the Gordon site (described in Section 2.0) in the PROJ-WB include: the open pit, MRSA, ore stockpile and overburden storage areas. It is assumed that the above facilities will have external drainage controls that prevent natural drainage from coming into contact with Project components and becoming contact water. The model differs from the BL-WB in that areas directly changed due to Project facilities use runoff coefficients to represent flow pathways in place of the SRM for non-Project areas.

Catchment areas for the open pit, overburden storage area, ore stockpile and MRSA were delineated based on the site plan (see Map 1-2, Appendix A). It is assumed that these catchment areas do not change during operation through to active closure.

The model was run dynamically on a daily time step and results are presented on a monthly reporting period for average, 25-year wet and 25-year dry climate scenarios (see Section 3.3.2) for the construction, operation, active closure, and post-closure phases.

Conceptual models showing the interactions of the Project components during operation, active closure, and post-closure are presented in Figure 3-10 to Figure 3-12 (Appendix B). To simulate post-closure, the PROJ-WB was extended to run until Year 128.

A key assumption that is made for decommissioning/closure is that once operation is finished, water from the collection pond is pumped to the open pit until the pit fills and begins to discharge to Farley Lake. All other contact water if not still draining to the collection pond, is also re-routed to the open pit.

3.3.2 Project Water Balance Inputs

3.3.2.1 Climate Scenarios

An evaluation of climate and hydrologic data for the Project was previously presented by Stantec (2017a). For the PROJ-WB precipitation data from Environment Canada's Lynn Lake climate station (Climate ID 5061646) were used to generate the climatic conditions for average, 25-year wet, and 25-year dry climate scenarios.

The climate normals data for period 1981 to 2010 were used to represent average climatic conditions. For the 25-year wet and 25-year dry return scenarios, annual precipitation data was fit to the log normal probability distribution. The result of the 25-year dry and 25-year wet year precipitation analysis is provided in Table 3-9. The same average annual lake evaporation used in the BL-WB and presented in Section 3.2.3.1 was used.

Table 3-9 Average Climate, Wet-Year and Dry-Year Climate Scenarios

Parameter	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Year
Average Year Total Precipitation (mm)	20.3	16.3	19.8	24.1	37.3	61.8	85.4	68.8	61	37.6	26.8	18.8	478
25-Year Dry Precipitation (mm)	14.6	11.7	14.3	17.4	26.9	44.5	61.5	49.6	44.0	27.1	19.3	13.5	344
25-Year Wet Total Precipitation (mm)	27.8	22.4	27.1	33.0	51.1	84.7	117.1	94.3	83.6	51.6	36.7	25.8	655

3.3.2.2 Runoff Coefficients

For areas changed by Project infrastructure, runoff coefficients were used to transform precipitation into surface runoff taking into consideration relief, surface storage, vegetation cover, evaporation, evapotranspiration, and infiltration losses. Runoff represents all surface water flows originating from overland flow, direct precipitation to waterbody surfaces, interflow and groundwater discharge. Table 3-10 presents the runoff coefficients used in the PROJ-WB for various mine infrastructure facilities.

Table 3-10 Facilities Runoff Coefficients used in PROJ-WB

Parameter	Runoff Coefficient
Ponds	1.0
Open Pit Wall	0.95
Natural Ground	0.40
Disturbed Ground	0.85
Overburden	0.40

Climate in the Project area is continental with lengthy cold winters. Very little surface runoff occurs during the winter months. Accumulated winter precipitation (snow) is released largely as surface runoff during the spring freshet and is accounted for in the precipitation-runoff factors presented in Table 3-11. This process is modelled by applying a monthly precipitation-runoff factor that accounts for how much of the available precipitation becomes runoff in a particular month (Table 3-11). The monthly precipitation-runoff factor was developed using the approximate monthly values of snowmelt and runoff generated by the SRM during baseline conditions and using the precipitation data. Available runoff represents the current month's precipitation plus the remaining fraction of water from the previous month's precipitation that did not became actual runoff, as it accumulated as snow (thus not available for runoff).

The surface runoff from the mine infrastructure facilities is estimated as the product of precipitation, precipitation runoff factors and runoff coefficients. The balance of the precipitation that is not allocated to runoff is carried over to the next month.

Table 3-11 Precipitation-Runoff Factors used in the PROJ-WB

Month	Precipitation-Runoff Factor	Month	Precipitation-Runoff Factor
January	0.01	July	1.0
February	0.01	August	1.0
March	0.01	September	0.95
April	0.01	October	0.50
May	0.40	November	0.05
June	0.98	December	0.01

3.3.2.3 Groundwater

Groundwater discharge to the lakes and lake discharge to the groundwater system were predicted for Gordon, Farley and Susan lakes during the construction, operation and decommissioning/closure phases of the Project using a hydrogeological model developed for the site (Stantec 2020b).

An estimate of groundwater discharge to the lakes during the phases of mining is presented in Table 3-12. The groundwater discharge to the lakes and lake discharge to groundwater were used as inputs to the lake components of the water balance. For additional details of the groundwater modelling results with respect to groundwater changes during phases of the Project refer to Stantec 2020b.

Table 3-12 Estimated Groundwater Discharges for Mine Phases (Stantec 2020b)

Lakes	Groundwater to Lake (m^3/s)	Lake to Groundwater (m^3/s)	Net Groundwater Inflow (m^3/s)
Construction			
Susan Lake	0.00062	0.00002	0.00060
Gordon Lake	0.00055	0.00591	-0.00536
Farley Lake	0.00389	0.01130	-0.00741
Operation			
Susan Lake	0.00054	0.00002	0.00051
Gordon Lake	0.00044	0.01090	-0.01046
Farley Lake	0.00387	0.01830	-0.01443
Decommissioning/Closure - Active Closure and Post-Closure			
Susan Lake	0.00041	0.00005	0.00037
Gordon Lake	0.00064	0.00021	0.00043
Farley Lake	0.00483	0.00206	0.00277

Details of the open pit groundwater inputs are explained in Section 3.3.2.4.

3.3.2.4 Open Pit

Model inputs to the open pit include groundwater inflow, precipitation and runoff that occurs within the open pit and evaporative losses from ponded water within the open pit. During operation, groundwater inflow, precipitation and runoff that accumulates in the open pit will be pumped to the collection pond. This water will require management as part of open pit dewatering. The following provides a summary of the model assumptions and input parameters.

Groundwater Inflow

Groundwater inflow rates to the open pit were predicted using the numerical groundwater flow model developed for the Project (Stantec 2020b). Figure 3-13 (Appendix B) shows the average groundwater inflow rates to the open pit during construction and operation. Due to open pit wall freeze up, groundwater inflow rates are generally low in winter compared to spring, summer and fall months. During operations, water from dewatering of the open pit will be pumped to a collection pond. Note that groundwater inflow to the pits is greatly reduced due to the operation of the interceptor wells.

Legacy Pit Dewatering Rates

In the PROJ-WB, open pit dewatering rates were calculated for each mining year. Initial dewatering of Wendy and East pits will be pumped to Farley Lake during construction. A pump rate of 1,700 m^3/day was assumed to dewater Wendy Pit and 3,950 m^3/day East Pit. It is estimated to take around 620 days (~20 months) to dewater both pits.

Open Pit Filling

Dewatering of the open pit is terminated in Year 5, after which water within the open pit is allowed to accumulate as a result of groundwater inflow, direct precipitation, and runoff from portions of the PDA and the collection pond. The groundwater inflow rates were modelled using results of the groundwater flow model (Stantec 2020b).

To accelerate the filling of the open pit, water from the collection pond will be directed to the open pit beginning in Year 6 (when the dewatering stops) until the pit is filled to the closure design elevation. After the pit is full, overflow will be directed to Farley Lake if it meets receiving environment water quality guidelines.

Interceptor Wells

The construction and operation of the open pit will require the open pit to be dewatered. This will also include dewatering from a series of groundwater interceptor wells installed between the open pit and Gordon and Farley lakes. The dewatering of the open pit and interceptor wells will result in the drawdown of the water table by up to 1 m over an area extending approximately 1,200 m around the open pit (Stantec 2020b).

A total of thirteen interceptor wells have been incorporated into the Project to intercept groundwater flowing to the pit. The wells were added to reduce the volume of contact water due to the Project, to mitigate potential project effects related to water quality and quantity and to maintain lake elevations in Gordon and Farley lakes. Approximately 95% of the of water pumped by the interceptor wells is Expected to be sourced from the lakes, with the remainder sourced from the bedrock. The wells were included in the model according to the pumping rates shown in Table 3-13 and Table 3-14. During construction and operation, the pumping rate is determined annually, which is initially related to the dewatering of the legacy mine pits and then to the development of the new pit (specifically pit depth). During active closure, the volume of water pumped from the wells is dependent upon the water elevation in the filling pit. At the end of operation, a small portion (~5%) of the groundwater from the interceptor wells is redirected towards the pit, as this is in excess to what is required to maintain lake levels.

During operation, the water from the interceptor wells will be directed to either Gordon Lake or Farley Lake. During decommissioning/closure (active closure and post-closure) while the pit is refilling, the interceptor well pumping rate is reduced as water elevation in the pit increases, reducing groundwater inflow rates, until the pit lake elevation reaches around 310 metres above sea level (masl).

Table 3-13 Interceptor Wells – Pumping Rates during Construction and Operation

Mine Year	Pumping Rate (m^3/s)	
	to Farley Lake	to Gordon Lake
-2	0.0969	0.0834
-1	0.0959	0.0828
1	0.0953	0.0825
2	0.095	0.0827
3	0.0949	0.0829
4	0.0949	0.0829
5	0.0949	0.0829
6	0.0949	0.0829

Table 3-14 Interceptor Wells – Pumping Rates during Closure

Pit lake elevation during filling (masl)	Pumping Rate (m³/s)	
	to Farley Lake	to Gordon Lake
115	0.0949	0.0829

300	0.0102	0.0089
305	0.0075	0.0066
310	0.0049	0.0042

3.3.2.5 Site Catchment Areas

Catchment areas for runoff and seepage collection from the open pit, ore stockpiles, MRSA and overburden stockpile were calculated for the operation and decommissioning/closure phases. The areas are summarized in Table 3-15 and the timing when each area is active in the model is determined from the schedule in Table 2-1. It was conservatively assumed that all surface water in the catchment areas is contact water and requires management. The contact water is directed either to the collection ponds via collection ditches or to the open pit.

Table 3-15 Catchment Areas used in PROJ-WB

Project Components	Gordon Site surface areas (km²)		
	Site	Natural Ground	Total Area
Open Pit	0.29	0.00	0.29
Ore	0.05	0.00	0.05
MRSA	0.77	0.24	0.10
Overburden	0.17	0.04	0.21

3.3.2.6 Project Changes to Watershed Areas

Streamflow during operations and decommissioning/closure (active closure and post-closure) were simulated using the PROJ-WB. Table 3-16 presents the area of each sub-watershed modelled using the SRM calculations for the BL-WB and the area using the runoff coefficient model.

Table 3-16 Summary of Watershed Area Changes within the PDA due to the Project

Sub-Watershed Name	Model Name	Waterbodies and Project Components within Watershed or Sub-Watershed	Total Baseline Area (km²)	Area Modelled using Runoff Coefficients (km²)	Area Modelled using SRM – BL-WB (km²)	Tributary to

Notes:

The catchment areas for watersheds ws-FAR3-SIM1, ws-FAR3, ws-FAR2-WHI1, ws-FAR1, and ws-SUS4 are not affected by Project components and are not listed here.

n/a* - no lake coverage or proposed project components exist within this sub-watershed

3.3.2.7 Mine Rock Storage Area

A conceptual model of flow through the MRSA was developed to model evaporation, infiltration, and runoff in the MRSA through all mine phases (Stantec 2020c). Key inputs and assumptions for the analysis were:

- The MRSA is divided in two components: slopes and central portion.
- The central portion is sub-divided in two sub-surface flow components: macropore flow and micropore flow.
- Infiltration is split between lateral seepage (toe seepage) and groundwater recharge at the base of the MRSA.

Figure 3-14 (Appendix B) presents a schematic of the flow pathways for water around and within the pile. A simple evaporation, runoff and infiltration model was used for the slopes, the macro/micropore flow paths were not modelled. It is assumed that this process will have less effect on flows, particularly at the toe of the slope where the thickness of the slope approaches zero.

The flow behavior through the MRSA depends on the wetting phase, which is dependent on time and whether the MRSA is covered. Flow behavior through the MRSA depends on the following temporal conditions:

- *Wetting*: time during which a wetting front is progressing through the MRSA. The mine rock is initially placed dry, and the wetting process continues over the years following placement. The wetting process was not modelled for the slope, for a similar reason that separate macro/micropore flow paths were not considered.

- *Wet*: the wetting front has broken through the base of the pile and the infiltration and unsaturated hydraulic conductivity profile of the material has reached an equilibrium. Steady state has been reached
- *No-cover*: There is no cover over the MRSA.
- *Cover*: there is a cover over the MRSA. The wetting process continues when the cover is in place.

The stages of MRSA development were defined as follows:

I **Wetting + No-Cover**: occurs during construction, operations and closure

II **Wetting + Cover**: occurs during the first 25 years of post-closure. The 25-year time length has been assumed (Stantec 2020c)

III **Wet + Cover**: occurs following 25 years (i.e., after Stage II) of post-closure

Table 3-17 outlines the proportion of total precipitation that is routed through the MRSA per the flow paths shown on Figure 3-14 (Appendix B). Every division of flow is proportionally calculated using the percentages shown in Table 3-17, according to the wetting phase (**I**, **II** or **III**), and the stockpile section (slope, macropore, micropore).

The following example can be used to explain how the data from the table is used:

To calculate surface flow on the MRSA slope for the stage **II** (wetting + cover), in the table select:

- row: “Surface flow” (Flow 2)

- column section: “a.slope”

- column: “**II**”

Value = 60% - which is the percentage to be applied to the calculated Flow 1 (Effective precipitation).

Table 3-17 MRSA Water Balance

Process	Flow	a. Slopes			b. Micropores			c. Macropores		
		I	II	III	I	II	III	I	II	III
Effective Precipitation	1	50%	50%	50%	50%	45%	45%	same as Micro		
Surface flow	2	60%	60%	60%	0%	60%	60%			
Infiltration	3	40%	40%	40%	100%	40%	40%			
Macro vs Micro	4	doesn't apply			91.3%	100%	100%	8.7%	0%	0%
Macro to toe	5.1				doesn't apply			60%	0%	0%
Macro to recharge	5.2							40%	0%	0%
Micro to toe	6.1	60%	60%	60%	60%	60%	60%	doesn't apply		
Micro to recharge	6.2	40%	40%	40%	40%	40%	40%			

Details of the MRSA water balance estimates are provided in the MRSA modelling memorandum attached in Stantec 2020c. Surface runoff and toe seepage are collected in the contact water collection ditches surrounding the MRSA and directed to the collection pond. The efficiency of the ditches is assumed to be 100% and the recharge is lost to the environment.

3.4 PROJECT WATER BALANCE RESULTS

3.4.1 Overview

The PROJ-WB combines the components of the BL-WB with components developed to model areas changed by the Project. The BL-WB provides estimates of streamflow for watersheds in the LAA under existing conditions. The PROJ-WB provides estimates of flow for the mine facility and incorporates the mine plan and water management features of the mine into the baseline environment. The PROJ-WB also incorporates results from groundwater modelling (Stantec 2020b) and runoff and seepage from key Project components. Runoff from the site infrastructure was estimated using modified model components developed for the PROJ-WB. The PROJ-WB was used to estimate streamflow and lake level during the construction, operation, active closure, and post-closure phases of the Project.

3.4.2 Baseline Water Balance Results

The calibrated BL-WB was used to model baseline flows and lake levels for the Gordon LAA. The baseline streamflows for the average, 1:25 dry, and 1:25 wet climate scenarios are summarized in Table 3-18.

3.4.3 Project Water Balance Results

The results of the PROJ-WB for average and the 25-year wet and dry climate scenarios are discussed next for each of the Project components.

3.4.3.1 Open Pit

Flow components into the open pit include groundwater seepage and direct precipitation, evaporation and dewatering. Figure 3-15 to Figure 3-17 (Appendix B) present the average monthly groundwater inflow rate and flows from direct precipitation, contribution from natural ground for climate average, 25-year dry, and 25-year wet climate scenarios to the open pit. The total dewatering rates and losses due to evaporation are also presented.

Under the average climate scenario, monthly average dewatering rates from the pit are 2,394 m^3/day with a maximum of 8,998 m^3/day. Under 25-year dry and 25-year wet climate scenarios the monthly average dewatering rates are 2,316 m^3/day with a maximum of 8,186 m^3/day, and monthly average of 2,491 m^3/day with maximum of 8,202 m^3/day, respectively. Pit dewatering is directed to the collection pond. Groundwater inflow rates to the pit range from 0 m^3/day to 8,909 m^3/day.

At the end of operations, dewatering of the open pit is terminated, the pit is allowed to fill with water from groundwater inflow, direct precipitation, surface contact water runoff (directed into the pit at this stage), and water from collection pond. Once water levels within the pit reach the final design elevation, water from the pit lake will be directed to Farley Lake. The model results demonstrate that it will take 12, 11 and 9 years to fill the open pit after the end of operation under 25-year dry, average and 25-year wet climate scenarios, respectively. Figure 3-18 (Appendix B) presents the pit filling over time for the three climate scenarios. Once the pit is filled, the annual mean monthly overflow rate from the pit lake ranges from 463 m^3/day (5.4 L/s) to 2,201 m^3/day (25.5 L/s) under average climate conditions (see Table 3-19). The mean monthly pit lake overflow rates for 25-year dry and 25-year wet climate scenarios range from 419 m^3/day to 1,576 m^3/day and 520 m^3/day to 3,026 m^3/day, respectively.

Table 3-19 Open Pit Overflow Average Monthly Discharge Rates (m^3/day) Post-Closure – All Climate Scenarios

Case	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual Average
Average	607	649	704	2,201	777	958	773	1,135	1,127	671	463	549	884
25-Year Dry	523	553	593	1,576	327	372	302	704	877	569	419	481	608
25-Year Wet	718	775	851	3,026	1,371	1,731	1,396	1,704	1,458	806	520	638	1,249

3.4.3.2 MRSA and Collection Pond

Runoff and toe seepage from the MRSA is collected in a series of ditches and ultimately pumped to the collection pond. Similarly, open pit dewatering is directed to the collection pond.

During operation, water from the pond is discharged to Farley Lake after the discharge water quality requirements are met. The mean monthly discharge ranges from the collection pond to Farley Lake, for the three different climate scenarios, and the mining stage are shown in Table 3-20. Figure 3-19 to Figure 3-21 (Appendix B) present the inflows and outflows of the collection pond for the three climate scenarios.

Table 3-20 Discharge from Collection Pond to Farley Lake (m^3/s) – All Climate Scenarios

Climate Scenario	Construction		Operation	
	min	max	min	max
Average	61	1896	384	9152
25-year dry	44	4387	296	8297
25-year wet	84	1923	298	8464

3.4.4 Results for Streamflow and Lake Level

The BL-WB was developed to predict streamflow for sub-watersheds within the Gordon LAA under existing conditions and during the same temporal and climate scenarios modelled for Project effects (i.e., the PROJ-WB). Flows and lake levels under existing conditions were used as the benchmark against which Project-related changes during the construction, operation, active closure and post-closure phases were assessed. The model predictions of streamflow and lake levels for baseline conditions and during the life of Project are presented below.

3.4.4.1 Streamflow

Average monthly and mean annual flow changes during construction, operation, and decommissioning/ closure (active closure and post-closure) from the baseline conditions are provided in Table 3-21 to Table 3-24, and graphically in Figure 3-22 to Figure 3-25 (Appendix B). Monthly and mean annual flow changes during construction, operation, and decommissioning/closure under the baseline conditions for average, 25-year dry and 25-year wet climate scenarios are provided in Appendix C.

Gordon Lake (QF03)

Results for predicted streamflows under baseline and Project conditions for the average climate scenario are presented in Table 3-21. The changes in mean annual flow for each Project phase are:

- Construction: Mean annual flow increases 0.001 m^3/s from baseline (0.02m^3/s). The interceptor wells, which start functioning with construction (Year -2) are the main reason for this change.
- Operation: Mean annual flows are Expected to increase 0.002 m^3/s from baseline (0.021 m^3/s). The interceptor wells are the main reason for this change.
- Active Closure: Mean annual flow decreases 0.002 m^3/s from baseline (0.021 m^3/s) during the active closure phase. The reduction in flow from Gordon Lake is due to the reduction in total drainage area that drains into the Gordon Lake, as parts of the this now drains towards the pit.
- Post-Closure: Mean annual flow decreases 0.003 m^3/s from baseline (0.021 m^3/s) during the post-closure phase, which is considered a negligible change. The reduction in flow at Gordon Lake outflow is associated with the reduction in total drainage area that drains into the Gordon Lake.

Farley Lake (QF05)

Results for predicted streamflows under baseline and Project conditions for the average climate scenario are presented in Table 3-22. The changes in mean annual flow during each Project phase are:

- Construction: Mean annual flow is Expected to increase 0.06 m^3/s over baseline (0.091 m^3/s) during the construction phase. The reason for this change is associated with the inflow from groundwater interceptor wells and the additional flow from dewatering of the legacy pits.
- Operation: Mean annual flow is Expected to increase 0.04 m^3/s from baseline (0.091 m^3/s) during operation. The reason for this change is associated with the inflow from groundwater interceptor wells as well as additional groundwater related to pit dewatering.
- Active Closure: Mean annual flow decreases 0.005 m^3/s from baseline (0.091 m^3/s) during the active closure phase, which is considered negligible.
- Post-Closure: Mean annual flow change is an increase of 0.002 m^3/s from the baseline during post-closure, which can be considered negligible.

Swede Lake (QF07)

Results for predicted streamflows under baseline and Project conditions for the average climate scenario are presented in Table 3-23 . The changes in mean annual flow for each Project phase are:

- Construction: Mean annual flow increases 0.060 m^3/s from baseline (0.192 m^3/s) during construction. The increase in streamflow at Swede Lake is associated with the additional water from the interceptor wells and the dewatering of the legacy pits.

- Operation: Mean annual flow increases 0.04 m^3/s from baseline (0.192 m^3/s) during operations. The increased streamflow is a result of the interceptor wells and from pit dewatering.

- Active Closure: Mean annual flow decreases 0.005 m^3/s compared with baseline (0.192 m^3/s), which is considered as negligible.

- Post-Closure: Mean annual flow increases by 0.002 m^3/s from baseline condition (0.192 m^3/s), which is considered to be negligible.

Ellystan Lake (QF08)

Results for predicted streamflows under baseline and Project conditions for the average climate scenario are presented in Table 3-24. The changes in mean annual flow for each Project phase are:

- Construction: Mean annual flow increases 0.06 m^3/s from baseline (0.304 m^3/s) during construction. The increase in streamflow at Ellystan Lake is associated with the increased water from the interceptor wells and dewatering of the legacy pits.

- Operation: Mean annual flow increases 0.04 m^3/s from baseline (0.304 m^3/s). The main reason for this change is the operation of the interceptor wells and pit dewatering.

- Active Closure: Mean annual flow decreases by 0.005 m^3/s from baseline (0.304 m^3/s), which is considered negligible.

- Post-Closure: Mean annual flow increases by 0.002 m^3/s from baseline (0.192 m^3/s), which is considered negligible.

3.4.4.2 Lake Levels

Gordon Lake

Results for predicted lake level under baseline and Project conditions for the average climate scenario are presented in Table 3-25. The changes in mean annual lake level for each Project phase are:

- Construction: Mean annual lake levels increase 0.03 m from baseline. The interceptor wells, which start functioning in Year -2, are the main reason for this change.
- Operation: Mean annual lake level is Expected to increase by 0.03 m from baseline. This change is associated with the interceptor wells.
- Active Closure: Mean annual lake level decreases 0.01 m from baseline. The reduction in the lake level at Gordon Lake is associated with the reduction in total drainage area that drains into the Gordon Lake as it is redirected towards the pit.
- Post-Closure: Mean annual lake level decreases 0.02 m from the baseline condition during the post-closure phase. The reduction in lake level at Gordon Lake is associated with the reduction in total drainage area that drains into the Gordon Lake, during the time that the pit is still filling. Under average climate scenario, the pit starts to spill over in Year 16.

Farley Lake

Results for predicted lake level under baseline and Project conditions for the average climate scenario are presented in Table 3-26. The changes in mean annual lake level for each Project phase are:

- Construction: Mean annual lake level is Expected to increase 0.14 m over baseline. The increase in water level at Farley Lake is associated with the inflow from groundwater interceptor wells and the additional flow from dewatering of the legacy pits.
- Operation: Mean annual lake level is Expected to increase 0.11 m from baseline. The increase is related to the inflow from groundwater interceptor wells and pit dewatering.
- Active Closure: Mean annual lake level deceases 0.01 m from baseline. This change is associated with all contact water being routed to the pit.
- Post-Closure: Mean annual lake level increases 0.01 m from baseline. This change is initially associated with the interceptor wells, and then with outflow from the new pit lake.

Swede Lake

Results for predicted lake level under baseline and Project conditions for the average climate scenario are presented in Table 3-27. The changes in mean annual lake level for each Project phase are:

- Construction: Mean annual lake level increases 0.05 m from baseline. The increase in water level at Swede Lake is associated with the inflow from groundwater interceptor wells and the additional flow from dewatering of the legacy pits.
- Operations: Mean annual lake level increases 0.04 m from baseline. The increased lake level is a result of the interceptor wells and pit dewatering.
- Closure: Mean annual lake level change is lower than 0.01 m, which is considered negligible.
- Post Closure: Mean annual lake level is lower than 0.01 m, which is considered negligible.

Ellystan Lake

Results for predicted lake level under baseline and Project conditions for the average climate scenario are presented in Table 3-28. The changes in mean annual lake level for each Project phase are:

- Construction: Mean annual change in lake level increases 0.02 m from baseline. The increase in water level at Ellystan Lake is associated with the inflow from groundwater interceptor wells and dewatering of the legacy pits.
- Operation: Mean annual lake level increases 0.02 m from baseline. The increased lake level is a result of the interceptor wells and pit dewatering.
- Closure: Mean annual lake level change is lower than 0.01 m, which is considered negligible.
- Post Closure: Mean annual lake level change is lower than 0.01 m, which is considered negligible.

Predicted lake levels for the baseline conditions and during the Project life (construction, operation, active closure and post-closure phases) are also presented in Figure 3-26 to Figure 3-28 (Appendix B) for Gordon Lake, Farley Lake, Simson Lake, Swede Lake and Ellystan Lake. respectively.

Table 3-25 Predicted Lake Level for Existing and Project Conditions for Gordon Lake - Average Climate Scenario

4.0 WATER QUALITY MODEL

4.1 BASELINE WATER QUALITY MODEL

4.1.1 Conceptual Model

The contaminant transport module of GoldSim was used to build a water quality model (WQM) directly linked to the WB.

The general approach was to:

- Use the BL-WB and baseline water quality monitoring data to develop a baseline water quality model (BL-WQM) that predicts water quality in lakes and streams.
- Verify the model by comparing the downstream predicted water quality in lakes and streams with that predicted by the BL-WQM.

The BL-WQM consists of network of individual cells representing catchments (undeveloped areas and areas of historical mine features) and lakes, connected by links (channels). An example of this network is shown on Figure 4-1 (Appendix B) for baseline conditions of the Gordon site. The catchments are defined using the watersheds delineated in the BL-WB (Map 3-2) and are sometimes split into smaller areas in order to attribute different water quality concentrations which reflect the influence of baseline conditions (e.g., historical mine features).

Catchments are defined as source cells with concentration as inputs to the BL-WQM. The volume inputs for these source cells are irrelevant because concentration is constant. These cells are shown in grey and blue in Figure 4-1 (Appendix B). Blue source cells represent natural or non-contact catchments and grey source cells represent contact or historic project components. Advective mass flux from a cell is determined as concentration in the source multiplied by an outflow rate (runoff) determined in the BL-WB. The BL-WQM transfers mass from source cells to mixing cells representing reservoirs, ponds, lakes and river sections.

The mixing cells are shown in orange on Figure 4-1 (Appendix B). Mixing cells represent selected lakes that are being modelled to assess the effect of the Project. The labels in each cell (e.g., “QF01_CT”) represent a naming convention for the BL-WQM that relates to a lake water quality monitoring station or a lake sub-catchment. The chemical concentrations in each mixing cell are variable and depend on mass inflow/outflow and cell volume, which considers ice formation in the modelled lakes (to capture the cryo-concentration effect). The flows and volumes of water in the mixing cells are determined in the BL-WB with values directly used in the BL-WQM.

Mass was added and removed to mixing cells to simulate reactions and seasonal variability as described in Section 4.1.3.4.

4.1.2 Model Structure

The BL-WQM structure is shown in Figure 4-1 (Appendix B). The watersheds and lakes are modelled to simulate conditions within the LAA. The model includes the chain of lakes from Gordon Lake to Farley Lake to Swede Lake and to Ellystan Lake, at the downstream extent of the LAA. Simpson Lake is modelled as a source cell with constant concentration because it does not receive any flow from lakes affected by the Project. Concentrations of various parameters (e.g., sulfate) in East and West parts of Farley Lake are consistently different indicating that Farley Lake is not well-mixed between the upstream (Farley Lake West) and downstream (Farley Lake East) basins. Therefore, Farley Lake was split into two cells representing the East and West parts of the lake (Figure 4-1, Appendix B).

Gordon Lake receives runoff from historic North MRSA with flows calculated from BL-WB. This lake is also affected by groundwater seepages from South MRSA (0.02 m^3/day) and North MRSA (1 m^3/day) based on results from the groundwater model (Stantec 2020b). Farley Lake receives surface runoff from both South and North MRSAs and groundwater seepage from the South MRSA (3.17 m^3/day).

Background groundwater inflows to the Gordon and Farley lakes were modelled as source cells with constant concentrations for bedrock. The groundwater inflows from these cells and groundwater outflows from lakes were defined in Section 3.2.3.5.

4.1.3 Water Quality Model Inputs

4.1.3.1 Parameter Selection

The selection of parameters for inclusion in the model was based on the results of the geochemical characterization presented in Stantec 2017c and 2020d, and criteria listed in the following federal and provincial regulatory documents:

- *Canadian Water Quality Guidelines* (CWQG) for the Protection of Freshwater Aquatic Life (FAL) by Canadian Council of Ministers of the Environment (CCME 2019).
- *Manitoba Water Quality Standards Objectives and Guidelines* (MSOG) for Freshwater Aquatic Life (FAL) by Manitoba Water Stewardship (MWS 2011).
- *Metal and Diamond Mining Effluent Regulations of the Fisheries Act* (MDMER 2018).

In addition to the parameters listed in these documents, the supporting parameters such as general water chemistry were added. The full list of parameters and applicable guidelines have been provided in (Table E-1, Appendix E).

Temperature and pH were not modelled but were required for calculations of CWQG values for aluminum and un-ionized ammonia. Although pH was not modeled, concentrations of proton, acidity and alkalinity were tracked by the model for potential future geochemical modelling outside of GoldSim, if needed. It should be noted that pH values below 6.0 are not Expected in ponds or reservoirs based on geochemical testing data and monitoring of the historical pit lakes and historic MRSAs (Stantec 2017c, 2020d).

Potentially acid generating (PAG) materials (rock and tailings) will be blended with non-PAG materials having excess of neutralization potential to prevent development of acidic drainage reduce metal mobility from Project components as discussed in Stantec (2017c, 2020d).

4.1.3.2 Chemistry Inputs

For each sub-catchment, a surface water quality monitoring station was selected as a source input (see Table E-2, Appendix E). Groundwater quality inputs were based on monitoring wells representing different sources, such as natural or historical components. The water quality inputs were prepared using following steps:

Step 1: Detection Limits

Concentrations of some elements were reported below detection limits (Stantec 2020e). For measured concentrations below detection limit, the full detection limit was used for the model inputs.

Step 2: Grouping and Checking Seasonal Data

Surface water concentrations were grouped by season for selected stations as follows:

- Spring: May and June
- Summer: July and August
- Fall: September and October
- Winter: November, December, January February, March and April

Concentrations for elements which are currently exceeding or close to the exceedances in the receiving environment, according to on baseline water quality monitoring data (Stantec 2020e) were checked for outliers for each season. Outliers were removed if they were suspected to be caused by sampling/analytical error prior to calculation of statistics. The values impacted by outlier removal are highlighted in Appendix F.

Step 3: Calculation and Adjustment of Statistics

For surface water, average and 95th percentiles were calculated for each station and season. In some stations, when no samples were available for the season (e.g., when a stream was frozen to the bottom), statistics from the preceding season were used (Appendix F). For related parameters, the adjustments of statistical inputs where made to confirm that the fraction of metals and species were not above the sum of these fractions (e.g., total ≥ dissolved fraction for the same element). The adjustments we made using following conditions:

- If dissolved fraction > total, then dissolved fraction = total fraction
- If dissolved Chromium (Cr) VI (hexavalent) > dissolved Cr, then dissolved Cr VI (hexavalent) = dissolved Cr

- If free cyanide > Weak Acid Dissociative (WAD) cyanide, then free cyanide = WAD cyanide
- If WAD cyanide > total cyanide, then WAD cyanide = total cyanide
- If nitrite (as N) > nitrate + nitrite (as N), then nitrite (as N) = nitrate + nitrite (as N)

The adjusted values are highlighted in Appendix F.

For groundwater concentrations, average concentrations were calculated for each monitoring well from baseline monitoring (Stantec 2020f). These averages were grouped to represent different groundwater units/sources: background bedrock, background overburden, and groundwater associated with historical features. For each group, geomean and log_{10} of 95^{th} percentile of the average concentrations were calculated assuming geometrical distribution due to heterogeneity of groundwater quality (Appendix F). Groundwater was filtered prior to sampling and therefore represents dissolved concentrations. It was assumed that statistics for dissolved concentrations in groundwater are the same for total concentrations of metal that discharges to surface water considering natural filtration as water moves through geological units.

4.1.3.3 Legacy Mine Features

Gordon Lake receives groundwater seepages from South (0.02 m^3/day) and North (1 m^3/day) MRSAs based on the groundwater model (Stantec 2020b). Farley Lake receives runoff from both South and North MRSAs and groundwater seepage from South MRSA (3.17 m^3/day). Groundwater inflows were set the same for all cases, while respective concentrations were geomeans or log_{10} of 95^{th} percentiles depending on selected case (Appendix F).

4.1.3.4 Mass Addition and Removal

Seasonal changes in water quality are also related to turnover and fast changes of redox conditions in the lakes, which are complex and parameter-specific processes. Removal and addition of mass in the lake was included to reproduce the seasonal changes occurring in lakes based on observed data, which will be potentially influenced by surface water discharges from the Project (Gordon, Farley, Swede and Ellystan lakes). The removal and addition of mass in the lakes was completed using the following steps:

1) Baseline model was run for average case with average climate scenario and average baseline concentrations inputs using daily timestep without any removal or addition of the mass.

   Monthly removal fraction of mass inflow in lakes ($F_{removal}$) was calculated using modeled average monthly concentrations (C_{model}) and observed seasonal concentrations as $F_{removal}$ = ($C_{observed}$ - C_{model})/C_{model} for each month of year. If removal fraction for a parameter was negative, it was set to zero.

2) To avoid the potential for removal to result in the fraction of metals and species being above the sum of these fractions (e.g., total fraction of the element must be greater than or equal to the dissolved fraction for the same element), adjustments were made using the following conditions:

a. If dissolved fraction removal < total, then dissolved fraction removal = total fraction removal
b. If dissolved Cr VI (hexavalent) removal < dissolved Cr removal, then dissolved Cr VI (hexavalent) removal = dissolved Cr removal
c. If free cyanide fraction removal < WAD cyanide fraction removal, then free cyanide removal = WAD cyanide removal
d. If WAD cyanide removal < total cyanide removal, then WAD cyanide removal = total cyanide removal
e. If nitrite (as N) removal < nitrate + nitrite (as N) removal, then Nitrite (as N) removal = nitrate + nitrite (as N) removal

3) Mass addition was calculated only for parameters showing negative values for removal rate. Annual mass addition (M_{added}) was calculated as average from observed seasonal concentrations ($C_{observed}$), lake volume (V_{model}) and modeled mass in the lake (M_{model}) as follows $M_{added} = C_{observed} \times V_{model} - M_{model}$.

4) To make sure that the addition of mass did not result in fraction of metals and species being above the sum of these fractions, adjustments were made using the following conditions:

a. If dissolved fraction addition > total, then dissolved fraction addition = total fraction addition
b. If dissolved Cr VI (hexavalent) addition > dissolved Cr addition, then dissolved Cr VI (hexavalent) addition = dissolved Cr addition
c. If free cyanide fraction addition > WAD cyanide fraction addition, then free cyanide addition = WAD cyanide addition
d. If WAD cyanide addition > total cyanide addition, then WAD cyanide addition = total cyanide addition
e. If nitrite (as N) addition > nitrate + nitrite (as N) addition, then Nitrite (as N) addition = nitrate + nitrite (as N) addition

5) The resulting mass was generally added once per year at the end of November or May when sudden changes were often observed in the data.

6) The model was run with calculated removal fraction and mass additions. Removal fraction and mass additions were adjusted or redistributed between months for a better match between predicted and observed concentration seasonal trends for selected parameters.

The steps were repeated to generate removal fraction and mass additions for a dry Upper Case (scenario) with inputs for 1:25 year dry climate scenario and 95th percentile baseline concentrations inputs. The resulting removal fractions of mass inflows and mass additions to the lakes are presented in Appendix G.

4.1.4 Verification of Baseline Water Quality Model

Modelled concentrations in Gordon, Farley, Swede and Ellystan Lakes were compared to observed concentrations using relative percent of difference (RPD):

$$RPD = (C_{model} - C_{observed})/C_{observed} \times 100\%$$

For the Expected Case, modelled concentrations were compared to average observed values, while 95th percentile of observed concentrations were used to calculate RPDs for the Upper Case. Positive RPDs indicate that the model overpredicts concentrations, which indicates that the model is conservative for this parameter (Table E-3 and Table E-4, Appendix E). Negative RPDs show that the model underestimates existing concentration inputs into the lakes. Modelled predictions for the concentrations of some elements were underestimated by 50% to 0% of observed concentrations. This was considered acceptable considering natural variability, errors of laboratory analysis and data manipulation for the inputs. Predictions for conservative parameters that are generally present in dissolved form such as fluoride, sulfate, and sodium regardless of season are well within 50% of observed concentrations indicating mass flow is adequate in the model. Potential reasons for some results being below 50% (RPD<-50%) are as follows:

- Dissolved fractions of aluminum, copper, cadmium, iron, lead and zinc are generally underestimated due to conditions set for the inputs such that the model will not predict dissolved concentrations above total concentration.
- Inputs for Upper Case use 95th percentile concentrations, which might be affected by outliers for some parameters regardless of the data pre-screening.
- Many parameters such as cyanide species, nitrite, chromium, cadmium, selenium, silver, and other metals measured close to the detection limits, result in analytical errors up to 100% which is within 3 times above reportable detection limits.

Other studies have observed similar differences between modelled and observed date. Bird et. al (1992) predicted water quality in Canadian Shield lakes and reported discrepancies between modelled and observed concentrations as follows:

- Phosphorous, (bio)reactive parameter, was within a factor of two (200%) of observed.
- Calcium, relatively conservative (unreactive) major cation, was underpredicted by 20-30%.
- Cadmium, relatively reactive trace metal, was underpredicted by 70-90%.

This shows that the differences between the modelled and observed parameters are less than those reported by Bird et. al (1992), thus it is concluded that the model presented here represents baseline conditions well.

4.2 PROJECT WATER QUALITY MODEL

4.2.1 Model Overview

To model water quality effects, the project water quality model (PROJ-WQM) is built upon operational flow rates and reservoir volumes calculated in the PROJ-WB. The PROJ-WQM integrates Project-specific source terms into the PROJ-WB to estimate water quality generated from the proposed mine components for each phase: construction, operation, active closure and post-closure (Figure 4-2 to Figure 4-5). The

PROJ-WQM inputs were prepared for Expected Case where average concentrations and leaching rates were used and for the Upper Case associated with 95th percentile inputs for concentrations and assumptions resulting in elevated leaching rates. These inputs are described in the following sections.

4.2.2 Historic Pit Lakes

The Wendy and East pit lakes are meromictic pit lakes with low dissolved oxygen content (DO), with elevated concentrations of iron (Fe) and arsenic (As) in the lower anoxic zone of the pits. Mean concentrations (C_{mean}) for shallow and deep portions of Wendy (AQF4) and East (AQF6) pit lakes are presented in Appendix F. The pit lakes will be mixed with compressed air prior to dewatering to increase DO to a level safe for fish (Stantec 2019). The introduction of compressed air will result in reduced concentrations of iron through oxidation and precipitation of iron oxyhydroxides. Experimental oxidation of samples from the anoxic zone shows that 10-30% of arsenic can also coprecipitate with iron solids. The concentrations (C) of elements in the mixed pits were averaged using a volume (V) weighting approach for shallow and deep parts of the pit lakes, using *Equation 4-1*.

$$C_{MIXED} = (C_{SHALLOW} \times V_{SHALLOW} + C_{DEEP} \times V_{DEEP})/(V_{SHALLOW} + V_{DEEP}) \quad \textit{Equation 4-1}$$

The resulting concentrations in the mixed pits were applied to the discharges from Wendy and East pit lakes during construction except for iron, arsenic and aluminum. Concentrations of total and dissolved iron in the discharges were limited to 0.374 mg/L, which is the maximum concentration observed in oxygenated portions of the pits (Figure 4-6, Appendix B). Based on experimental oxidation of pit samples, it is assumed that 30% and 10% of total and dissolved arsenic will be removed in the pit lakes, in Expected and Upper Cases, respectively. Both pit lakes will be discharged into the western basin of Farley Lake. It was assumed that most of the suspended Fe and As will stay at the bottom of the pits and during pit development and operation this sediment-rich water will be pumped to the collection pond and settle in there.

4.2.3 Interceptor Wells

Six interceptor wells will be located on the east side of the open pit which will discharge to Gordon Lake, and seven wells will be located on west side of the open pit and discharge to Farley Lake West. Interceptor wells start pumping from the beginning of construction (see Figure 4-2, Appendix B).The pumping rate was estimated to be 14 L/s for each well. More details on the interceptor wells can be found in Stantec (2020b). In the PROJ-WQM model wells stop operating during the closure phase when the pit lake is 50 m below overflow (full pit lake) level in order to provide opportunity stratification of the pit lake as discussed in section 4.2.9 (Figure 4-5, Appendix B). In reality. Interceptor well pumping rates will start declining once this elevation is reached, however pumping will not be shut down until pit lake elevations remain stable.

The groundwater model estimates that the average travel time from Gordon Lake to interceptor wells on the east side of the open pit is 490 days and 730 days from Farley Lake to wells of the east side of the open pit (Stantec 2020b). Before the water from the lakes arrives at the pit, the geomean and log_{10} of 95th percentiles bedrock concentrations were used as input for well water quality for the Expected and Upper Case, respectively. When travel time is exceeded, the concentrations from the respective lakes were mixed with groundwater concentrations proportional to flows calculated in the PROJ-WB model.

4.2.4 Open Pit

Open pit outflow represents a mixture of groundwater and net precipitation inflows with the addition of mass leached from mine rock, pit wall and undetonated explosives. The numerical groundwater model indicates that groundwater consists of approximately 80% water that has originated from bedrock and the remaining 20% from overburden (Stantec 2020b). Therefore, concentrations from selected bedrock wells were applied to 80% inflow and overburden well concentrations were applied to 20% of groundwater inflows. Geometric mean and $\log_{10}$ of 95^{th} percentiles concentrations from these groups of wells were used as input for Expected and Upper Case, respectively (Appendix F). Additional groundwater discharges to the pit are discussed in Section 4.2.10 and shown on Figure 4-3 to Figure 4-5 with dotted line.

Mine water receives additional mass from:

1) Elements leached from rock rubble pit and pit walls as a result of weathering, and

2) Nitrogen species leached from undetonated explosives.

4.2.4.1 Exposed Rock Inputs

To account for mass input, it was assumed that the 3D surface of ultimate open pit (436,100 m^2) was covered with 1 m mine rock with a density of 2.3 t/m^3 resulting in approximately 1 Mt of rock exposed during operation. This is a conservative assumption and is often used in industry (Golder 2014). Element leaching rates from (R) exposed rock mass were based on average rates estimated from field bin tests and by scaling factors (SF) and using *Equation 4-2*:

$$R = M \times R_{FIELD\ BIN} \times SF_{SURFACE\ AREA} \qquad \textit{Equation 4-2}$$

Where:

M = 1,003 kilotonnes rock mass of rock exposed in the open pit, based on pit area, thickness of rubble and mine rock density

$R_{FIELD\ BIN}$ = three year (2015-2018) average weighted leaching rates from field bins applied to construction, operation and closure, while the last year (2018) average weighted leaching rates were used as inputs for the post-closure. Field bin weighting was done based on percentages of lithologies in the open pit. The Banded Iron Formation (BIF) lithology is represented by two composite samples (S5J and S5FI). This results in different leaching rates for post-closure conditions (i.e., 2018 leaching rates). Therefore, the lower rate from sample S5J is used to derive the average rate ($R_{FIELD\ BIN}$) for the Expected Case. The lower rate is incorporated because it is assumed to be representative of neutral conditions which are Expected to be maintained as a result of operational blending of PAG and non-PAG rock. For Upper Case, it is assumed that the higher leaching rates (e.g., for arsenic) in the post-closure phase could be related to acidification in pockets of PAG rock, which represents up 22% of the mass. Therefore, for the Upper Case scenario at decommissioning/closure, it is assumed that 22% of the leaching rate (PAG BIF) is approximated by S5FI sample and 37% of the leaching rate is approximated by sample S5J (non-

PAG BIF). The loading rates approximated by the remaining rock types are similar to the Expected Case loading rates (Table E-5, Appendix E).

$SF_{SURFACE\ AREA}$ = scaling factor for rock surface area. Rock in field bins were crushed to - ¼” and it was scaled up to represent blasted rock, which is coarser and has smaller surface area. The surface areas were calculated from particle site distributions (PSD) assuming spherical particles and density of 2.3 t/m^3. Mine rock PSD were taken from the Diavik mine studies (Smith et al. 2013) and resulted in 1.94 m^2/kg. This area was used for average case scaling, while a higher value of 3 m^2/kg was selected for the Upper Case based on experience with similar mine sites. Average surface area of crushed rock in field bins was 34.1 m^2/kg as calculated from average weighted PSD for each lithology. Dividing surface areas of blasted rock by average weighted surface areas for crushed mine rock in field bins, $SF_{SURFACE\ AREA}$ of 0.057 for Expected Case and 0.088 for Upper Case were used in Equation 4-2.

4.2.4.2 Blasting Residues

Mass rate of lost (non-exploded) nitrogen (R_N, g/yr) was calculated using *Equation 4-3*:

$R_N = MR \times PF \times F_N \times L_N \times FR_N$ *Equation 4-3*

Where:

MR is the total mining rate of ore + mine rock t/yr, (Table C-6)

PF = 300 g/t, is the Powder Factor based on the Mine Plan

F_N = 0.333, is the fraction of nitrogen in the explosive based on 1/3 of nitrogen in the explosive (Bailey et al. 2012) dimensionless

L_N = 0.002 for Expected and 0.01 for Upper Cases, based on 0.2% nitrogen of total nitrogen used loss from Ferguson and Leask (1988) and 1% as maximum observed in dry open pit mines in Table A-4 from Golder (2008)

FR_N = 0.1 (10%), is the fraction of nitrogen released from rock and ore while in the open pit, prior material transfer to storage areas, this assumes that another 90% will be leached in storage areas (Golder 2007).

The leached nitrogen was speciated as follows based on recommendations from Ferguson and Leask (1988):

- For Expected Case: N-NH3 - 11%; N-NO3 - 87%; N-NO2 – 2%
- For sensitivity case: N-NH3 - 4%; N-NO3 - 95%; N-NO2 – 1%.

This speciation was also applied to nitrogen leached from mine rock and ore stockpiles as described in Sections 4.2.5 and 4.2.6. The release of nitrogen species was assumed to be instant in mine water.

Leaching rates of nitrogen species and elements from rock weathering were explicitly added to cell OP_CT representing the open pit. The volume of this cell was calculated using PROJ-WB. Mine water will be collected in sumps at the bottom of the open pit and pumped to a collection pond. During closure and post-closure phases, the open pit will be filled, eventually forming a pit lake, which is described below in Section 4.2.9.

4.2.5 Mine Rock Storage Areas

The leaching rates from proposed MRSA (MRSA _CT) were calculated using Equations 4-2 and 4-3 and inputs are shown in Table E-6 (Appendix E). The calculated total leaching rate ($R_+ R_N$) was released to porewater stored in the MRSA cell to provide the concentration inside the MRSA at each time step. The volume of pore water was calculated from the PROJ-WB (see Section 3.3.8) assuming that one year of infiltration to matrix is stored until material in the MRSA is wetted. When mine rock is fully wetted, the volume of infiltrating water equals outflow from MRSA. In the model, porewater leaves the MRSA cell as both toe seepage and recharge to groundwater with the mass proportioned to each pathway based on outflow percentages shown in Table 3-17. The mass associated with runoff and toe seepage is captured by the ditches and directed to the collection pond. The mass associated with groundwater recharge directed to the open pit or environmental receptors based on the results of the groundwater flow model (Stantec 2020b). During construction, operation and closure the mine rock pile is assumed to be fully oxygenated similar to field bins. Element leaching rates from mine rock (R) should decline in post-closure because cover will limit oxygen ingress into the interior of the stockpile resulting in reduction of sulfide oxidation. For post-closure, element leaching rates from (R) covered rock mass was calculated using *Equation 4-4*:

$$R = (M_{>10m} \times SF_{>10m} + M_{<10m} \times SF_{<10m}) \times R_{FIELD\ BIN} \times SF_{SURFACE\ AREA} \qquad \textit{Equation 4-4}$$

Where:

$M_{>10m}$ = 36,740 kilotonnes, rock mass in upper 10 m of the stockpile

$M_{<10m}$ = 13,335 kilotonnes, rock mass located below 10 m of the stockpile surface

$SF_{>10m}$ - reduction scaling factor in upper 10 m of the mine rock stockpile

- For Expected Case: 0.71 in spring, summer and fall and 0.24 in winter
- For Upper Case: 0.85 in spring, summer and fall and 0.31 in winter

$SF_{>10m}$ - reduction scaling factor in mass located below 10 m of the stockpile surface

- For Expected Case: 0.42 in spring, summer and fall and 0.4 in winter
- For Upper Case: 0.54 in spring, summer and fall and 0.42 in winter

These scaling factors were calculated assuming first order kinetics for sulfide oxidation (Elberling and Nicholson 1996). As input, the oxygen content from monitoring of mine rock at Detour mine was used, the mine rock has similar sulfide content to the rock at Gordon and 0.5 m of soil cover

(Steinepreis 2017). During operation and closure this factor is equal to 1, which conservatively assumes no reduction in leaching rate.

- For the definition of $R_{FIELD\ BIN}$ and $SF_{SURFACE\ AREA}$ inputs refer to definitions provide in Equation 4-2.

Calculated pore water concentrations in mine rock were limited for dissolved and total iron at 0.49 mg/L, and total and dissolved aluminum – 0.085 mg/L based on maximum observed concentrations in oxygenated historical ponds (Figure 4-6). The reason for capping these elements is that they are Expected to precipitate as hydroxides and partially settle within the pile. Fluoride showed high leaching rates in field bin S2C resulting in high predicted concentrations that have never been observed at the site regardless that this lithology has been mined before and is present in the historical mine features. Therefore, fluoride was capped at 0.61 mg/L as maximum concentration observed in field bin S2C, which is approximately six times higher than concentrations observed in historical ponds (Figure 4-6). Similar to fluoride, predicted arsenic was much higher for the post-closure of the Upper Case than maximum observed concentration (0.034 mg/L) in historical features and kinetic tests (Figure 4-6). The limit for total and dissolved arsenic in porewater was conservatively set at 0.1 mg/L which is ~3x higher than the maximum observed value.

4.2.6 Ore Stockpile

The leaching rates from ore stockpile (Ore_cell _CT) were calculated using equations 4-2 and 4-3 and inputs shown in Table E-5 and Table E-6 (Appendix E). The volume balance for the cell representing ore stockpile was calculated using the same approach as for MRSA.

4.2.7 Overburden Stockpile and Runoff

For the overburden storage, existing overland runoff quality (average of inputs from stations AQF10 and AQF23) was assumed for overburden stockpile. Runoff from overburden stockpile is directed to the collection pond during operation and closure.

4.2.8 Collection Pond

The collection pond receives mass from mine water pumped from the open pit and from discharges from MRSA, ore and overburden storage areas during construction and operation. During these phases, the pond discharges to the western basin of Farley Lake. During closure and post-closure, the discharge is diverted to the open pit. The solubility limits of MRSA pore water were applied to the pond.

4.2.9 Pit Lake

During closure and post-closure the open pit will be filled, forming a pit lake as described in section 3.4.3.1. Major sources of elements for the pit lake are the collection pond and the groundwater inflow with minor contribution from pit walls and rubble on benches, which eventually become submerged. The pit lake filling was modeled as follows:

- Fully mixed lake is assumed until the level reaches an elevation of 50 m below the spillway elevation.

- When lake reaches level of 50 m below the spillway elevation, discharge from collection pond is sent via pipe to the pit below this elevation. The pit lake stratifies because collection pond discharge water is denser than groundwater, most of which enters the upper portion of the pit lake based on groundwater model (Stantec 2020b). The upper portion of the lake (epilimnion) is set to reach maximum 16m depth estimated on the geometry of the pit and existing (Wendy and East) pit lakes. The upper portion of the pit lakes also receives mass loading from pit walls and rubble on benches. This loading gradually reduces in the pit lake as these features are submergence. There is an additional mass of soluble metal fraction flushed from submerged rubble to the upper portion of pit lake Table E-7 (Appendix E).

- Upper portion of pit lake starts do discharge to Farley Lake West when the level of the lake reaches spillway elevation. At this point, collection pond is allowed to discharge to upper portion. As a result, the upper layer of the pit become denser and the pit lake eventually destratifies as predicted total dissolved solids concentration in the layers.

The residence time in the pit lake is estimated to be over 100 years based on water balance for normal conditions. The long residence time in the pit lake results in a reduction in concentration of contaminants through degradation (e.g. denitrification), uptake by algae coagulation/flocculation of suspended particles and further sedimentation. Removal or transfer rates from water to sediment were estimated from available literature. The transfer rates assumed in the model are generally lower, more conservative, than average values reported in the literature (Table E-8, Appendix E). The removal of the elements was limited to the upper 16 m of the pit lake, where photosynthesis and algae growth is Expected to occur.

4.2.10 Groundwater Discharges

Potential subsurface contamination, sourced from Project components (e.g., ore stockpile or MRSA), are not Expected to reach the closest natural receptors such as Gordon and Farley lakes for at least 300 years based on the groundwater model (Stantec 2020b). In post-closure, the pit lake and Susan Lake are Expected to receive 300-yr averaged flows of 0.3 m^3/day and 8.7 m^3/day from the MRSA, respectively.

5.0 WATER QUALITY PREDICTIONS

5.1 REPORTING OF CASES

Water quality predictions are presented for two cases/scenarios:

- Expected Case inputs include average and geometric mean concentrations for surface and groundwater, respectively. This case considers average leaching rates from mine rock in post-closure, which assumes no development of localized acidic conditions as a result of successful management of PAG materials.

- Upper Case inputs include 95^{th} percentiles and $\log_{10}$ of 95^{th} percentiles concentrations for surface and groundwater, respectively. This case assumes elevated leaching rates due to development of localized acidic conditions during post-closure. However, overall pH of seepage is Expected to stay neutral.

Both cases assume average climate and 1 year of wetting scenario for MRSA to faster reach steady state concentrations in pore water of mine rock. Additional sensitivity runs showed that water quality predictions for dry and average climate inputs are similar. This comparison showed that that water quality model is less sensitive to the flow and more sensitive to chemistry inputs including both baseline and Project.

The prediction statistics for each month of each phase of the Project of the Expected Case and Upper Case for water quality for point source discharges are summarized in Table 5-1 to Table 5-6, and for the receiving environment are provided in Appendix H. These summaries only include modeled parameters of interest (POI); these parameters are regulated by the guidelines listed in Table E-1 (Appendix E), regardless of exceedances. Time series (trends) for POI in the discharges are included in Appendix I. The long-term federal and provincial guidelines on the plots for discharges are not applicable, as the guidelines are developed for the receiving environment, and are shown just for comparison. Appendix I also includes trends in the receiving environment for parameters exceeding federal or provincial freshwater quality guidelines.

The predicted water quality of bed seepage (i.e., not captured in seepage collection ditches) from the MRSA are presented in Appendix J. The seepage water quality is not discussed in this report as diffuse groundwater inflow to the receiving environment is a not point-source discharge.

5.2 POINT SOURCE DISCHARGES

Point source discharges of contact water from the mine include:

- Wendy and East pit dewatering to West Farley Lake during construction.
- Interceptor wells to both Gordon and West Farley Lake from construction to post-closure.
- Collection pond to West Farley Lake during construction and operation.
- Overflow from the pit lake directly into West Farley Lake during post-closure (once the open pit is flooded). Initial overflow occurs from upper portion of stratified pit lake. When pit de-stratifies (mixes), chemistry of the discharge instantly changes and remains relatively stable after that (Appendix I).

Concentration summaries for POI in the discharges are shown in Table 5-1 to Table 5-6. The water quality model predicts that none of the parameters will exceed MDMER discharge limits and acute/short term federal and provincial guidelines in both the Expected and Upper Cases.

Table 5-1: Predicted concentrations of POI in discharge from Wendy Pit lake

[2]Predictions were screened against the future MDMER Schedule 4 limits coming into force on June 1, 2021 (see Section 9.1.1.1).
[3]The short-term MSOG-FAL for ammonia (as N) was calculated with a conservatively assumed pH of 8.5.

5.3 RECEIVING ENVIRONMENT WATER QUALITY

The direct receivers are Gordon Lake and the West basin of Farley Lake (Farley Lake West) during all phases of the Project. However, interceptor wells will only be discharging to Gordon Lake for approximately half year in the post-closure phase. After that, only Farley Lake West will receive overflow pit lake during post-closure. Downstream receivers are the East basin of Farley Lake (Farley Lake East), Swede Lake and Ellystan Lakes. Susan Lake is outside of the Project catchment and receives seepage from the MRSA during post-closure.

To facilitate discussion, the receiving environment is presented in the following order:

- Gordon Lake
- Farley Lake West
- Downstream receivers: Farley Lake East, Swede Lake and Ellystan Lakes.
- Susan Lake.

The water quality predictions for the receiving environment are compared against the long-term federal and provincial freshwater quality guidelines (CWQG and MSOG, respectively). For the parameters with variable guidelines (pH, hardness, and ect. dependent), mean monthly inputs were used for calculation. The parameters exceeding the guidelines are identified in Table 5-7 and Table 5-8 for the Expected and Upper Cases, respectively. In some cases, plots show marginal exceedances (e.g., manganese) that are not listed in these tables (Appendix I). The reason for that is that plotted guidelines are based on median annual inputs resulting in straight line for simplification, while tables are generated from guidelines that vary on monthly basis. The sections below are not intended to provide an assessment of Project effects on water quality, but rather to highlight predicted exceedances and to identify sources causing these exceedances.

5.3.1 Gordon Lake

Exceedances of fluoride (CWQG and MSOG), total phosphorous (MSOG) and total iron (CWQG and MSOG) are predicted in Gordon Lake for Expected Case. Phosphorous and total iron are naturally exceeded in the baseline, while fluoride is related to discharge from the groundwater interceptor wells. When wells are decommissioned, fluoride concentrations decline below CWQG and MSOG (Appendix I). In addition, total copper and dissolved manganese show marginal exceedances of the CWQG benchmarks for Upper Case. Copper is sourced from groundwater interceptor wells. Manganese is naturally above the CWQG in the lake.

5.3.2 Farley Lake West

Total phosphorous exceedances of MSOG for the Expected Case are predicted during construction only and are related to dewatering of the legacy pit lakes. In the Upper Case, sources of total phosphorous are dewatering wells and collection pond. In post-closure, discharge from the pit lake results in marginal exceedances in total phosphorous for both Expected and Upper Cases. Fluoride shows exceedances of

CWQG and MSOG during all Project phases for both cases. These exceedances are related to discharges from groundwater interceptor wells, collection pond and overflow from pit lake. Exceedances for total iron (CWQG and MSOG) are predicted for the Upper Case only. The major source of iron is groundwater interceptor wells, decommissioning of which results in the decline of concentrations to below the guidelines in post-closure. An exceedance of dissolved manganese (CWQG) is predicted only for the construction phase for the Upper Case and is related to dewatering of historical pit lakes.

5.3.3 Downstream Receivers

Total iron and total phosphorous are exceeded in the baseline predictions for Farley Lake East and Ellystan lakes for both cases. These baseline exceedances are not predicted for Swede Lake, which is located between Farley Lake East and Ellystan lakes, indicating that iron and phosphorous are controlled by local conditions of the lakes.

Fluoride exceedances are predicted for both cases in Farley Lake East in all Project phases, similar to Farley Lake West. Fluoride concentrations decline along a flow path in the downstream direction with no exceedances predicted to pass beyond Swede Lake for the Expected Case in any Project phase. In the Upper Case, fluoride exceeds guidelines during operations in all downstream receivers, but declines in Swede Lake and Ellystan Lake to below the guidelines during post-closure.

Dissolved manganese is naturally above the CWQG in Farley Lake East in the Upper Case. Elevated manganese is also related to dewatering of legacy pit lakes during construction.

5.3.4 Susan Lake

No exceedances were predicted in Susan Lake for the Expected Case. In the Upper Case, total iron and total phosphorous are exceeded CWQG and MSOG in the baseline predictions. There is very little change in these parameters related to subsurface non-point discharge from MRSA.

6.0 CONCLUSIONS

No parameters are predicted to exceed the MDMER discharge limits or short-term (acute) federal and provincial guidelines for discharges, even for the conservative Upper Case.

In the receiving environment, total copper, fluoride, total iron, dissolved manganese and total phosphorus, were predicted to exceeded long-term (chronic) federal or provincial guidelines for protection of aquatic life. Total iron, dissolved manganese and total phosphorus were predicted to exceed the respective guidelines under baseline conditions, which is consistent with water quality monitoring. However, concentrations of these parameters are predicted to increase in some receptors as result of the Project. Fluoride exceedances are related to the discharge from interceptor wells and collection pond, decommissioning of which (well and pond) results in a decline of fluoride in post-closure. Total copper is predicted to exceed federal guidelines only during the Upper Case and the primary source is from groundwater interceptor wells.

The assessment of the exceedances and proposed mitigations are discussed in Environmental Impact Statement/Environmental Assessment completed for the Project. This report provides inputs for that assessment. .

8.0 STANTEC QUALITY MANAGEMENT PROGRAM

This report, Lynn Lake Gold Project (LLGP) Hydrology and Water Balance and Water Quality Model Technical Modeling Report: Gordon Site, prepared for Alamos Gold Inc., dated April 30, 2020, was produced by Stantec Consulting Ltd.

This report was written by the following individual:

Gonzalo Donoso, P.Eng. (BC)
Senior Water Resources Engineer

Signature

Nikolay Sidenko, Ph.D., P.Geo. (MB)
Senior Environmental Geochemist

Signature

This report was reviewed by the following individuals:

David Luzi, Ph.D., P.Geo. (MB)
Senior Hydrologist

Signature

Approval to transmit to client:

Karen Mathers, M.Sc., P.Geo. FGC (MB), PMP
Senior Project Manager

Signature

This report was independently reviewed by Kara Hewgill, B.Sc., Principal.

9.0 LIMITATIONS

This Technical Modelling Report entitled Lynn Lake Gold Project Hydrology Water Balance and Water Quality Impact Assessment: Gordon Site was prepared by Stantec Consulting Ltd. (“Stantec”) for the account of Alamos Gold Inc. (the “Client”) to support the approvals and permitting process for the Lynn Lake Gold Project in Lynn Lake, Manitoba. In connection thereto, this document may be reviewed and used by the federal and provincial government agencies participating in the approvals and permitting process in the normal course of their duties; and stakeholders may provide comment as part of the regulatory approvals process. Except as set forth in the previous sentence, any reliance on this document by any third party for any other purpose is strictly prohibited. The material in it reflects Stantec’s professional judgment in light of the scope, schedule and other limitations stated in the document and in the contract between Stantec and the Client. The opinions in contents of the document are based on conditions and information existing at the time the document was published and do not take into account any subsequent changes. In preparing the document, Stantec did not verify information supplied to it by others. Any unauthorized use that a third party makes of this document is the responsibility of such third party. Such third party agrees that Stantec shall not be responsible for costs or damages of any kind, if any, suffered by it or any other third party as a result of decisions made or actions taken based on unauthorized use of this document.

Appendix E WATER QUALITY INPUT TABLES

Table E-1: Parameters selected for water quality model

Parameter name	Parameter Symbol	Name in model	Parameter group	Units	Guidelines/Limits		
					CWQG	MSOG	MDMER
pH	pH	pH	General chemistry	pH Unit	6.5-9.0	6.5-9.0	6.0-9.5
Proton	H+	Proton	General chemistry	mg/L	n/v	n/v	n/v
Acidity Total	Acid	Acidity_T	General chemistry	mg/L	n/v	n/v	n/v
Alkalinity Total	Alk	Alkalinity_T	General chemistry	mg/L	n/v	n/v	n/v
Bromide	Br	Bromide	General chemistry	mg/L	n/v	n/v	n/v
Chloride	Cl	Chloride	General chemistry	mg/L	120	n/v	n/v
Fluoride	F	Fluoride	General chemistry	mg/L	0.12	0.12	n/v
Sulfate	SO_4	Sulfate	General chemistry	mg/L	n/v	n/v	n/v
Phosphorus Total	P(T)	Phosphorus_T	Nutrients	mg/L	Narrative	0.025	n/v
Ammonia Nitrogen Total	$N\text{-}NH_3(T)$	N_Ammonia	Nutrients	N mg/L	Table 2	Equation*	n/v
Nitrite Nitrogen	$N\text{-}NO_2$	N_Nitrite	Nutrients	N mg/L	0.06	0.06	n/v
Nitrate and Nitrite Nitrogen	$N\text{-}NO_3+NO_2$	N_Nitrate_Nitrite	Nutrients	N mg/L	13	n/v	n/v
Cyanide Total	CN(T)	Cyanide_T	General chemistry	mg/L	n/v	n/v	0.5
Cyanide Free	CN(F)	Cyanide_F	General chemistry	mg/L	0.005	0.0052	n/v
WAD** Cyanide	CN(WAD)	Cyanide_WAD	General chemistry	mg/L	n/v	n/v	n/v
Hardness	Hard	Hardness	General chemistry	mg/L	n/v	n/v	n/v
Radium 226	Ra-226	Radium_226	Radioactivity	Bq/L	n/v	n/v	0.37
Total Suspended Solids	TSS	TSS	Supporting	mg/L	n/v	n/v	15
Aluminum Dissolved	Al(D)	Aluminum_D	Trace elements	mg/L	n/v	n/v	n/v
Aluminum Total	Al(T)	Aluminum_T	Trace elements	mg/L	0.005/0.1	0.005/0.1	n/v
Antimony Dissolved	Sb(D)	Antimony_D	Trace elements	mg/L	n/v	n/v	n/v
Antimony Total	Sb(T)	Antimony_T	Trace elements	mg/L	n/v	n/v	n/v
Arsenic Dissolved	As(D)	Arsenic_D	Trace elements	mg/L	n/v	0.15	0.3
Arsenic Total	As(T)	Arsenic_T	Trace elements	mg/L	0.005	n/v	0.3
Barium Dissolved	Ba(D)	Barium_D	Trace elements	mg/L	n/v	n/v	n/v
Barium Total	Ba(T)	Barium_T	Trace elements	mg/L	n/v	n/v	n/v
Beryllium Total	Be(T)	Beryllium_T	Trace elements	mg/L	n/v	n/v	n/v
Boron Dissolved	Be(D)	Boron_D	Trace elements	mg/L	n/v	n/v	n/v
Boron Total	B(T)	Boron_T	Trace elements	mg/L	1.5	1.5	n/v
Cadmium Dissolved	Cd(D)	Cadmium_D	Trace elements	mg/L	n/v	Equation*	n/v
Cadmium Total	Cd(T)	Cadmium_T	Trace elements	mg/L	Equation**	n/v	n/v
Calcium Dissolved	Cd(D)	Calcium_D	General chemistry	mg/L	n/v	n/v	n/v
Chromium Dissolved	Cr(D)	Chromium_D	Trace elements	mg/L	n/v	Equation*	n/v
Chromium Hexavalent Dissolved	Cr(VI)	Chromium_D_Hex	Trace elements	mg/L	0.001	0.001	n/v
Chromium Total	Cr(T)	Chromium_T	Trace elements	mg/L	0.0089	n/v	n/v

Table E-1: Parameters selected for water quality model

Notes:

The most stringent guideline was selected when two or more guidelines are established for the same parameter under the same jurisdiction (CCME, MWS, or Government of Canada).
CWQG - Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life (CWQG-FAL referred to as CWQG) by Canadian Council of Ministers of the Environment (CCME 2020).
MSOG - Manitoba Water Quality Standards Objectives and Guidelines for Freshwater Aquatic Life - Manitoba (MWS 2011).
MDMER - Metal and Diamond Mining Effluent Regulations (Canada), Schedule 4 - Authorized Limits of Deleterious Substances, Maximum Authorized Monthly Mean Concentrations (SOR/2002-222 2020).
ᵞ Guidelines are for pH; pH = - Lg[H^+] where [H^+] is a molar concentration of protons.
Equations were used to calculate hardness, pH, temperature, and DOC-dependent guidelines for these parameters as per MWS (Equation*) and CCME (Equation**):

- Total cadmium CWQG-FAL: at hardness > 280 mg/L the guideline is 0.00037 mg/L, at hardness between 17 and 280 mg/L the guideline (in mg/L) is 0.001*[10^(1.016*(log10(Hardness))-1.71)], at hardness < 17 mg/L the guideline is 0.00011 mg/L.
- Total copper CWQG: When the water hardness is 0 to < 82 mg/L the CWQG is 0.002 mg/L, at hardness ≥82 to ≤180 mg/L the CWQG is calculated as CWQG (μg/L) = 0.2 * $e^{\{0.8545[\ln(hardness)]-1.465\}}$, at hardness >180 mg/L the CWQG is 0.004 mg/L, if the hardness was unknown the CWQG was 0.002 mg/L.
- Total lead CWQG: When the hardness is 0 to ≤ 60 mg/L the CWQG is 0.001 mg/L, at hardness >60 to ≤ 180 mg/L the CWQG is calculated as CWQG (μg/L)= $e^{\{1.273[\ln(hardness)]-4.705\}}$, at hardness >180 mg/L the CWQG is 0.007 mg/L, if the hardness was unknown the CWQG was 0.001 mg/L.
- Dissolved manganese CWQG-FAL (mg/L): pH and hardness-dependent guideline calculated based on the CWQG and benchmark calculator in Appendix B or Table 5 of the Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life: Manganese (Dissolved) 2019 (CCME 2019).
- Total nickel CWQG: When the water hardness is 0 to ≤ 60 mg/L the CWQG is 0.025 mg/L, at hardness > 60 to ≤ 180 mg/L the CWQG is calculated as CWQG (μg/L) = $e^{\{0.76[\ln(hardness)]+1.06\}}$.
- Dissolved zinc CWQG-FAL: exp(0.947[ln(Hardness)] - 0.815[pH] + 0.398[ln(DOC)] + 4.625). The value for DOC was set at 0.3 mg/L (i.e., the lowest and most conservative value to calculate the guideline).
- Ammonia MSOG: $[(0.0577/1+10^{7.688-pH})+(2.487/1+10^{pH-7.688})]*a$, where a=2.85 or $a=1.45*10^{0.028*(25-Temperature)}$, whichever is less and pH ≥6.5 and ≤9.0.
- Dissolved cadmium MSOG (μg/L): $[e^{\{0.7409[\ln(Hardness)-4.719\}}]*[1.101672-\{\ln(Hardness)(0.041838\}]$.
- Dissolved chromium MSOG (μg/L): $[(e^{(0.819*(\ln(Hardness)) + 0.6848)})]*[0.86]$
- Dissolved copper MSOG (μg/L): $[e^{\{0.8545[\ln(Hardness)]-1.702\}}]*[0.960]$.
- Dissolved lead MSOG (μg/L): $[e^{\{1.273[\ln(Harness)-4.705\}}]*[1.46203-\{\ln(Hardness)(0.145712)\}]$.
- Dissolved nickel MSOG (μg/L): $[e^{\{0.8460[\ln(Hardness)]+0.0584\}}]*[0.997]$.
- Dissolved zinc MSOG (μg/L): $[e^{\{0.8473\{\ln(Hardness)]+0.884\}}]*[0.986]$.

Manitoba Tier II guidelines for dissolved metals are based on exceedance once in three years, but not more frequent, being acceptable during periods of infrequent and extreme low stream flows.

- CWQG for total phosphorus: Canadian Guidance Frameworks is used for total phosphorus (CCME 2014): ultra-oligotrophic <4 μg/L, oligotrophic 4-10 μg/L, mesotrophic 10-20 μg/L, meso-eutrophic 20-35 μg/L, eutrophic 35-100 μg/L, hyper-eutrophic >100 μg/L.
- Ammonia CWQG: pH and temperature-dependent guideline for total ammonia as N presented in Table 2 of the CWQG guidelines for the protection of aquatic life: Ammonia (CCME 2010). The values from Table 2 are multiplied by 0.8224 to convert them into total ammonia (as N).
- Ammonia MSOG-FAL: pH and temperature-dependent guideline, see Equation 1 values from Table 1 in MWS (2011).
- Nitrate and Nitrite Nitrogen: CWQG for nitrate is applied.
- Aluminum CWQG: 0.1 mg/L if pH>6.5, otherwise 0.005 mg/L.

Table E-2: Chemistry inputs to baseline model cells

Lake Catchment/Mixing cell (Station ID used for initial lake concentration*)	Subcatchment/Source Cell Description	Subcatchment/Cell ID in the water quality model	Water Quality Station ID Used for Source Cell Input*
Gordon_Lake_CT (AQF2)	Gordon Lake southern inlet	QF01_CT	AQF10

Table E-3: Baseline water quality model results for expected case

Notes:
Relative Percent Difference (RPD) values below -50% are highlited pink with dark red font colour.
Relative Percent Difference (RPD) values above 100% are highlited yellow with dark orange font colour.
T and pH are used for calculations of guidelines only and are not modeled.
CWQG - Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life (CWQG-FAL referred to as CWQG) by Canadian Council of Ministers of the Environment (CCME 2020).
CWQG for total phosphorus: Canadian Guidance Frameworks is used for total phosphorus (CCME 2020): ultra-oligotrophic <4 µg/L, oligotrophic 4-10 µg/L, mesotrophic 10-20 µg/L, meso-eutrophic 20-35 µg/L, eutrophic 35-100 µg/L, hyper-eutrophic >100 µg/L
CWQG for total zinc - most stringent guideline is applied using 0.3 mg/L of dissolved organic carbon (CCME 2020).
CWQG for total and dissolved manganese - most stringent long-term guideline is applied using the lowest hardnes as $CaCO_3$ (35 mg/L) and pH (6.70) (CCME 2019).
MSOG - Manitoba Water Quality Standards, Objectives, and Guidelines for Freshwater Aquatic Life (MSOG-FAL referred to as MSOG), long-term (MWS 2001).
MDMER - Metal and Diamond Mining Effluent Regulations (Canada), Schedule 4 - Authorized Limits of Deleterious Substances, Maximum Authorized Monthly Mean Concentrations (SOR/2002-222 2020).
MDMER is applied for total and dissolved metal concentrations for the purpose of the modeling.
Equation* - MSOG formula for calculation of hardness, pH, and temperature-dependent provincial guidelines (total ammonia as N and dissolved cadmium, chromium, copper, lead, nickel, and zinc) (MWS 2011).
Equation** - CWQG formula for calculation of hardness, pH, temperature, and DOC-dependent federal guidelines (total cadmium, copper, lead, manganese, nickel, and zinc) (CCME 2020).
Table 2 - CWQG guideline for total ammonia as N presented in Table 2 of the CWQG guidelines for the protection of aquatic life: Ammonia (CCME 2010). The values from Table 2 are multiplied by 0.8224 to convert them into total ammonia (as N).
Values exceeding CWQG are double underlined, MSOG are bold, and MDMER are highlighted yellow.
Observed T and observed pH is shown under the modeled T and pH, respectively.

Notes on last page

Table E-4: Baseline water quality model results for upper case

Notes:
Relative Percent Difference (RPD) values below -50% are highlited pink with dark red font colour.
Relative Percent Difference (RPD) values above 100% are highlited yellow with dark orange font colour.
T and pH are used for calculations of guidelines only and are not modeled.
CWQG - Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life (CWQG-FAL referred to as CWQG) by Canadian Council of Ministers of the Environment (CCME 2020).
CWQG for total phosphorus: Canadian Guidance Frameworks is used for total phosphorus (CCME 2020): ultra-oligotrophic <4 µg/L, oligotrophic 4-10 µg/L, mesotrophic 10-20 µg/L, meso-eutrophic 20-35 µg/L, eutrophic 35-100 µg/L, hyper-eutrophic >100 µg/L
CWQG for total zinc - most stringent guideline is applied using 0.3 mg/L of dissolved organic carbon (CCME 2020).
CWQG for total and dissolved manganese - most stringent long-term guideline is applied using the lowest hardnes as $CaCO_3$ (35 mg/L) and pH (6.70) (CCME 2019).
MSOG - Manitoba Water Quality Standards, Objectives, and Guidelines for Freshwater Aquatic Life (MSOG-FAL referred to as MSOG), long-term (MWS 2001).
MDMER - Metal and Diamond Mining Effluent Regulations (Canada), Schedule 4 - Authorized Limits of Deleterious Substances, Maximum Authorized Monthly Mean Concentrations (SOR/2002-222 2020).
MDMER is applied for total and dissolved metal concentrations for the purpose of the modeling.
Equation* - MSOG formula for calculation of hardness, pH, and temperature-dependent provincial guidelines (total ammonia as N and dissolved cadmium, chromium, copper, lead, nickel, and zinc) (MWS 2011).
Equation** - CWQG formula for calculation of hardness, pH, temperature, and DOC-dependent federal guidelines (total cadmium, copper, lead, manganese, nickel, and zinc) (CCME 2020).
Table 2 - CWQG guideline for total ammonia as N presented in Table 2 of the CWQG guidelines for the protection of aquatic life: Ammonia (CCME 2010). The values from Table 2 are multiplied by 0.8224 to convert them into total ammonia (as N).
Values exceeding CWQG are double underlined, MSOG are bold, and MDMER are highlighted yellow.
Observed T and observed pH is shown under the modeled T and pH, respectively.

Table E-5: Unscaled average weighted leaching rates from field bins

Table F-1: Water quality model results for expected case

Notes:
AQF1 to AQF38 are surface water sites.
T and pH are used for calculations of guidelines only and are not modeled.
Alkalinity and acidity are not modeled but tracked for potential future geochemical modeling.
NULL - no water was available for sampling.
Values highlighted yellow were flaged as discrepancies and resolved by removing outliers (values higher than Q3+1.5xIQR or lower than Q1-1.5xIQR, where Q3 is quartile 3, Q1 is quartile 1, IQR is inter-quartile range (Q3-Q1)) through application of water quality QAQC procedures.
n/v - no value or guideline is not established.
Assumptions:
If no analytical value was available then a zero value is used for the model, except for total metals, which are equal to dissolved metals.
If dissolved metal was greater than total metal then total metal concentration is used for the model (shown in green font).
If chromium VI was greater than dissolved chromium then dissolved chromium concentration is used for the model (shown in green font).
If free cyanide was greater than WAD cyanide then WAD cyanide is used for the model (shown in green font).
If WAD cyanide was greater than total cyanide then total cyanide is used for the model (shown in green font).

Table F-2: Water quality model results for upper case

Notes:
AQF1 to AQF38 are surface water sites.
T and pH are used for calculations of guidelines only and are not modeled.
Values highlighted yellow were flaged as discrepancies and resolved by removing outliers (values higher than Q3+1.5xIQR or lower than Q1-1.5xIQR, where Q3 is quartile 3, Q1 is quartile 1, IQR is inter-quartile range (Q3-Q1)) through application of water quality QAQC procedures.
n/v - no value or guideline is not established.
Assumptions:
n/v - no value or guideline is not established.
Assumptions:
If no analytical value was available then a zero value is used for the model, except for total metals, which are equal to dissolved metals.
If dissolved metal was greater than total metal then total metal concentration is used for the model (shown in green font).
If chromium VI was greater than dissolved chromium then dissolved chromium concentration is used for the model (shown in green font).
If free cyanide was greater than WAD cyanide then WAD cyanide is used for the model (shown in green font).
If WAD cyanide was greater than total cyanide then total cyanide is used for the model (shown in green font).

Appendix H SUMMARY OF WATER QUALITY MODEL PREDICTIONS

Summary Table

Appendix Title and Model Scenari	Notes	Cells Included
Gordon Site Receiving Environment Predicted Water Quality for the Expected Case	Monthly mean, median and maximums for each project phase; percent increase from baseline; Indicate parameters that exceed water quality guidelines CCME short: **Bold** CCME long: *Italic* MWQG short: Single Underline MWQG long: Grey Background	Gordon_Lake_CT, Farley_Lake_East_CT, Farley_Lake_West_CT, Susan_lake_CT, Swede_Lake_CT, Ellistan_Lake
Gordon Site Receiving Environment Predicted Water Quality for the Upper Case		Gordon_Lake_CT, Farley_Lake_East_CT, Farley_Lake_West_CT, Susan_lake_CT, Swede_Lake_CT, Ellistan_Lake
Gordon Site Contact Water Quality for the Expected Case	Monthly mean, median and maximums for each project phase; Indicate parameters that exceed water quality guidelines CCME short: **Bold** MWQG short: *Italic* MDMER: Single Underline	Collection_Pond, Upper_OP_CT, East_mixed, Wendy_mixed, Farely_wells_CT, Gordon_wells_CT
Gordon Site Contact Water Quality for the Upper Case		Collection_Pond, Upper_OP_CT, East_mixed, Wendy_mixed, Farely_wells_CT, Gordon_wells_CT

Notes for contact water discharges:

Dashed lines represent "not applicable" (no discharge)
Bold font indicates the monthly average concentration exceeds the short-term CWQG.
Italic font indicates the monthly average concentration exceeds the short-term MSOG.
Underline indicates monthly average concentration exceeds the metal and diamond mine effluent regulations.
CWQG-FAL = Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life by Canadian Council of Ministers of the Environment (CCME 2020).
MSOG-FAL = Manitoba Water Quality Standards Objectives and Guidelines for Freshwater Aquatic Life - Manitoba (MWS 2011).
[a] Manitoba Tier II guidelines for dissolved metals are based on exceedance once in three years, but not more frequent, being acceptable during periods of infrequent and extreme low stream flows.
* Equations were used to calculate hardness (as $CaCO_3$), pH, DOC, and temperature-dependent guidelines for these parameters as per MWS (2011) and CCME (2020).
- Ammonia MSOG-FAL: pH and temperature-dependent guideline. Values used for screening are based on Equation 1 values from Table 1 in MWS (2011)
- Ammonia CWQG-FAL: pH and temperature-dependent guideline. Values used for screening are based on Table 1 in CCME (2010) and converted to ammonia (as N) by multiplying the unionized ammonia (NH_3) guidelines by 0.8224.
- Dissolved cadmium MSOG-FAL (mg/L): 0.001*[(exp(0.7409*(ln(Hardness))-4.719))*(1.101672-(ln(Hardness)*0.041838))]
- Dissolved chromium MSOG-FAL (mg/L): 0.001*[(exp(0.819*(ln(Hardness)) + 0.6848))*(0.86)]
- Dissolved copper MSOG-FAL (mg/L): 0.001*[exp(0.8545[ln(Hardness)]-1.702]*[0.960]
- Dissolved lead MSOG-FAL (mg/L): 0.001*[(exp(1.273*(ln(Hardness)) - 4.705))*((1.46203-(ln(Hardness))*0.145712))]
- Dissolved nickel MSOG-FAL (mg/L): 0.001*[(exp(0.846*(ln(Hardness))+0.0584))*(0.997)]
- Dissolved manganese CWQG-FAL (mg/L): pH and hardness-dependent guideline. Values used for screening are based on Table 5 in CCME (2019).
- Dissolved zinc MSOG-FAL (mg/L): 0.001*[(exp(0.8473*(ln(Hardness))+0.884))*(0.986)]
- Dissolved zinc CWQG-FAL: exp(0.947[ln(Hardness)] - 0.815[pH] + 0.398[ln(DOC)] + 4.625). The value for DOC was set at 0.3 mg/L (i.e., the lowest and most conservative value to calculate the guideline)
- Total cadmium CWQG-FAL: at hardness > 280 mg/L the guideline is 0.00037 mg/L; at hardness between 17 and 280 mg/L the guideline (in mg/L) is 0.001*[10^(1.016*(log10(Hardness))-1.71)]; at hardness < 17 mg/L the guideline is 0.00011 mg/L.
- Total copper CWQG-FAL: at hardness > 180 mg/L the guideline is 0.004 mg/L; at hardness between 82 and 180 mg/L the guideline (in mg/L) is 0.001*0.2*[exp(0.8545*(ln(Hardness]))-1.465)]; at hardness < 82 mg/L the guideline is 0.002 mg/L.
- Total lead CWQG-FAL: at hardness > 180 mg/L the guideline is 0.007 mg/L; at hardness between 60 and 180 mg/L the guideline (in mg/L) is 0.001*[exp(1.273*(ln(Hardness]))-4.705)]; at hardness < 60 mg/L the guideline is 0.001 mg/L.
- Total nickel CWQG-FAL: at hardness > 180 mg/L the guideline is 0.15 mg/L; at hardness between 60 and 180 mg/L the guideline (in mg/L) is 0.001*[exp(0.76*(ln(Hardness]))+1.06))]; at hardness < 60 mg/L the guideline is 0.025 mg/L.
Significant figures do not correlate with the error of the modeling.
* Change between mean baseline and project in percent.

Notes for receiving environment:

Dashed lines represent "not applicable".
Bold font indicates the monthly average concentration exceeds the short-term CWQG.
Italic font indicates the monthly average concentration exceeds the long-term CWQG.
Underline indicates monthly average concentration exceeds the short-term MSOG.
Shaded background indicates the monthly average concentration exceeds the long-term MSOG.
CWQG-FAL = Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life by Canadian Council of Ministers of the Environment (CCME 2020).
MSOG-FAL = Manitoba Water Quality Standards Objectives and Guidelines for Freshwater Aquatic Life - Manitoba (MWS 2011).
[a] Manitoba Tier II guidelines for dissolved metals are based on exceedance once in three years, but not more frequent, being acceptable during periods of infrequent and extreme low stream flows.
* Equations were used to calculate hardness (as $CaCO_3$), pH, DOC, and temperature-dependent guidelines for these parameters as per MWS (2011) and CCME (2020).
